16. Trommels

ing screens or trommels (Fig 35) are today more used than any ough Ferraris and impact screens may take their place. A sloping, cylinder, of screen cloth or plates, if fed at upper end, will convey the y a helical path to lower end. Undersize drops into the housing be- ize being delivered at lower end. Results aimed at are: large capacity,

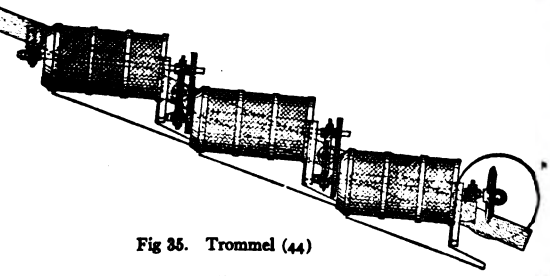

Fig 35. Trommel (44)

rfect a separation as possible of oversize from undersize. Factors in- e: length, diameter, slope, and rotative speed.

The longer the trommel, the greater its capacity, and the cleaner the sepa- it, as increased length does not decrease wear of screens, nor increase their ger the trommel, the greater the cost of replacing screens. Moreover, a very el has a thicker bank of oversize passing through it, not only increasing wear hat hindering the screening, but also requiring more driving power. Lengths from about 3 to 12 ft. The writer believes 9 ft to be about the best length.

r. A large diameter gives a thinner bank, therefore screens more freely; ar is less, because a smaller proportion of the screen takes the scour at any But, large diameter increases first cost, and cost of replacing worn screens The question in each case is whether saving from increased length and di- re than offsets the extra cost. Diameters are usually from 24 to 50 in, and believes about 42 in is best.

most important. Flat slope makes for long helical path, increasing time for ough screen; the bank is therefore thicker, scour of sand on metal greater,

creen (Fig 36), invented in Colo, has had its greatest success at Sulit- way. Screen is 5 ft diam by 3.5 ft long, of octagonal section, with inward eed, 12 rev per min. It is fed on the outside with wet ore, and through is washed . This de- tly reduces onsumption, repairs, and d separation

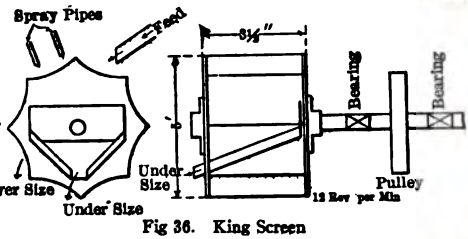

Fig 36. King Screen

l arrange- plest and best with coarsest d follow with rder of the size of hole. Each feeds its undersize to the next finer screen below. Dividing 2 groups, the coarser and the finer, and delivering the entire feed to the coarsest roup, sending its oversize to the coarser group, saves somewhat the diluting of he plan overworks the coarsest of the fine screens and complicates the mill. everal other schemes of screening, but all complicate the mill more than they work.

ale, screen sizes, screen analysis. Sizes of holes in screens, whether rcles, are measured in fractions of an inch or in millimeters (mm). The sizes of screens in a given mill form what is called the "sieve scale" of that mill. ld that there should be a definite ratio between these sizes, and suggested $\sqrt{2} =$ ratio for diameters of round holes or edges of square holes, giving a scale of: mm, 2 mm, and so on. The largest screen is first, the smallest last. For s this scale becomes 1 sq mm, 2 sq mm, 4, 8, 16, 32, and so on. An ore is d" when it has been screened first on the coarsest sieve, yielding oversize ze; and the undersize has been screened on next sieve, yielding oversize and nd so on down. The successive oversize products, and final undersize, ed, give the percentages of each size; and, if analyzed for the valuable metal, e "screen analysis" of the ore. Such a set of products is designated as fol- ct 1, through 32 mm on 22.6 mm; product 2, through 22.6 on 16, and so on. argument for a constant ratio is this: the difficulty of separating, in sub- centration, the smallest (22.6-mm) grain of galena, for example, from the mm) grain of quartz in the product "through 32 mm on 22.6 mm," is precisely the difficulty of separating the smallest (2.8-mm) grain of galena from the m) grain of quartz in the product "through 4 mm on 2.8 mm," and so on. hich seems wise and right, is not adopted in mills, because of the real or sup- ability of concentrating machines to treat almost any product brought to men therefore are inclined to adapt the sieve scale to the work of the mill; if, of two jigs, the one treating the coarser product is underworked, and er jig is overworked, on purchasing the next lot of screens they will get a r mesh, which will give more feed to the coarser and less to the finer jig. ther arguments also for changing the sieve ratio.

ests of trommels show how far from perfect is the screening done in e rush and over-crowding for maximum product is practiced, even if of screening falls off.

17. Classifiers

Classifiers are used to sort grains of different
a series of products of diminishing falling velo
subsequent treatment; also to separate sand fr
or slime. They deal with fine sizes better tha
screens in a mill, generally beginning at about

Principles. A classifier conveys sand and water i
pockets or depressions, from feed end to overflow

gots in the bottom, ranging from coarse in first spigot to fine in the last, the ing finest of all. Classification is improved by rising currents of water in op- the falling sands, graded from strongest current at first spigot to weakest in These currents prevent finer grains from being entangled with the coarser. An sing rising currents of clear water is a HYDRAULIC CLASSIFIER. The vertical 7) in which the rising current mainly acts is called the SORTING COLUMN. The t above the sorting column, which brings the feed, makes a rough separation, ws the light, rejected part, is called the POCKET. The enlargement below, which e clear hydraulic water, delivers the rising current to sorting column, and nd water to the spigot below, is called the PRESSURE BOX.

of hydraulic classifiers. They are capable of treating material om 8 mm (¾ in) to dust, but best work is done between 6.3 mm (¼ in) m (0.004 in.). For grains above 8 mm, the quantity of water in the xcessive; for grains finer than 0.1 mm, box classifiers (spitzkasten), nes and drag thickeners are best.

ydraulic classifier consists of a series of cones, one overflowing into used on products below 1 mm. Though often found in concentrating classifier violates a fundamental law of good classification; namely, elocity of rising current in any pocket, due to feed water and sorting- ater combined, must be equal to velocity in sorting column. If less, ns will be too heavy to rise with the overflow, but too light to settle ng column. These grains will form a troublesome bank, for which emedy is to slacken the rising current, and let down all grains which e into the overflow. This spoils the spigot product, because much also come down. To overcome this the cone may be fed by a plung- , which breaks up the bank and lifts it out; but some coarser grains in a previous spigot are carried into a following one by this device.

-cone hydraulic classifier, for products of 1 mm or less, attempts to the fault of the single cone by an inner conical baffle-plate, of slightly le than the outer, to equalize the rising velocity throughout. There extra adjustment for varying area of cross section of pocket; but ly one position giving a velocity uniform to the top.

ls vortex hydraulic classifier provides for all velocities by having ectional area of sorting columns computed to discharge the required

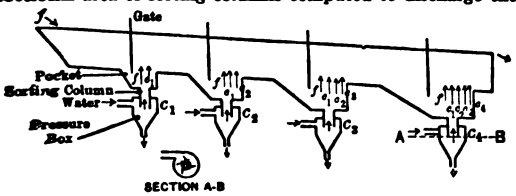

Fig 37. Richards Vortex Hydraulic Classifier

required velocity through each sorting column, and to lift the re- ume with required velocity in the pockets. Hence, no troublesome med. It can be used for sizes up to 6.3 mm (0.25 in), or even larger. od of computation for design of this classifier is shown in Table 51.

putations (54) involved in Table 51 are as follows: Line 1. Tons per 24 hr are obtained by a sizing test. Line 2. Feed and overflow are assumed. To get s of grains in the other products, we have 10 + 15 = 25 tons; 100 : 25 = 2.5 mm; 10 + 15 + 20 = 45; 100 : 45 = 2.5 mm: 1.15 mm; 10 + 15 + 20 + 25 = = 2.5 mm: 1.75 mm. Line 3. Kg per min are computed from tons per ultiplying by 0.631; thus 30 tons × 0.631 = 18.93 kg per min. Line 4. Ve-

the lower grains fell into the bulb; then the cur-
n quickened, the bulb removed, by pinching the rubber tube, and another
ce. This was repeated until all the material except some extremely fine
wn out into 45 bulbs. These products were dried, screen-sized, and weighed.
Dividing the av diam of the quartz grains in any bulb by that of the galena, the ratio of diameters under hindered-settling conditions was obtained. Discarding, as before, the heavier and the lighter spigot products, and taking only the intermediate (bulbs 19 to 34 inclusive), the final av ratio under hindered-settling conditions was found to be 6.92; that is, the av diam of the quartz grains was 6.92 times that of the galena, or nearly twice as great as the ratio under free-settling conditions.

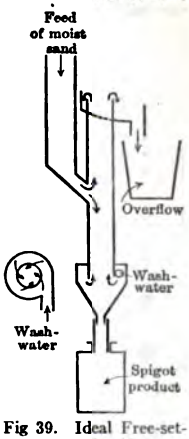

Fig 39. Ideal Free-settling Classifier

Thus, a FREE-SETTLING classifier has a launder or tank, a pocket for rough separation, a sorting column to finish separation, and a pressure box to deliver wash water up and spigot product down. A HINDERED-SETTLING classifier has all the above parts, together with a "teeter chamber" just above the sorting column or constriction. This chamber must in general hold some definite ratio of area to that of sorting column.

Hindered-settling classifier has the following advantages: Larger "added increment;" wider separation between the minerals when concentrated; more perfect separation of slime from spigot products; smaller water consumption than the free-settling classifier.

red-
(53)

42 explain the meaning of "added increment." In each diagram, at the
cal tube, in which grains of quartz and galena are supposed to have ar-
elves according to their settling ability; in Fig 41, under free-settling con-
g 42, under hindered-settling conditions. In each case the adjacent grains
spective ratios of diameter (see above). Therefore there is much more
the largest grain of quartz in the hindered-settling, than in the free-settling

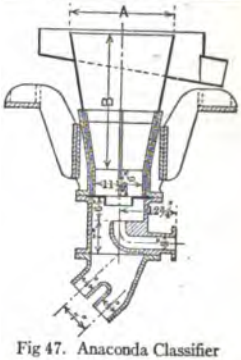

Fig 47. Anaconda Classifier

and-slime separator (Fig 48) is a pulsating, cone classifier, for separat- slime. It can divide on any point decided upon; that is, to settle against a 10, or 5, or 1 mm per sec current, the slower grains in each case going to overflow. Having a classifier capable of handling the quantity of feed water, it is then adjusted for the size desired. It must have a pulsating current, otherwise there will be a down current in one place and an up current in another. It has a screen plate on which is a bed of rounded pebbles, about 1 in diam. Thus far it has been proved only in the laboratory, doing good work there, and showing that by this principle, fine lines can be drawn between size of grain in the sand and in the slime.

ards Sand- rator (53)

Deister classifier (Fig 49) consists of a vertical series of conical, slotted diaphragms, enclosed in a slightly tapering barrel, through which rises a column of hydraulic water. This enters through radial holes in the ttom, and meets the descending grains of ore. The apparatus may ler the apex of a pointed box or conical settling tank, or under an ttom of a launder. Its principal merit is that the peculiar shape ragms, and the staggered position of the slots, afford such amp

STANFORD LIBRARIES

opportunity for light grains to be caught up and
ate volume of hydraulic water needs to be added

A satisfactory hydraulic classifier should be able so
Wilfley tables, that slime is completely eliminated from
remaining in their tailings.

18. Pulp Classifiers without H

These include: pointed boxes (spitzkasten),
sliming and dewatering cones, dewatering boxes
tanks. In a concentrating mill, after water has
mels, fine crushing machines, and hydraulic c
reached where it is unwise to add more water, bu
proximate classification according to size of the

Surface-current box classifier (Rittinger's
work (62).

Rittinger recommended: (*a*) For pulp of 1 mm an
per min: 1st box, 0.632 m wide by 1.897 m long; 2
long; 3d box, 2.529 m wide by 3.793 m long; 4th box, 5.058 m wide by 4.742 m long. (*b*) Ends of boxes should slope 50°, to prevent banking (sides to be steeper). (*c*) Goose-neck spigot, discharging 3 to 3.5 ft below water level for the first, and 2 to 2.5 ft below for last spigot. (*d*) To avoid banks, the launder feeding 1st box should have a slope of 1 to 1.5 in per 6 ft (Locke (45) found 5° slope for this); 2d box, 0.5 to 0.75 in p 6 ft; 4th box, 0.125 to 0.25 in per 6 ft. (*e*) Boxes 1 and

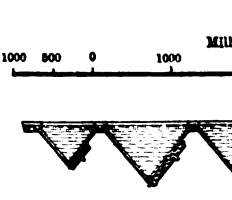

Fig 50. Ritti

4 to be hopper throughout, the spigots to be 0.25 in to 0.75 in diam, accordand. Delivery by spigots may be: 40% in 1st, 28% in 2d, 18% in 3d, 10% in overflow.

n spitzkasten. If feed pulp is flowed over the surface of clean water ak, the heavier grains will settle to the spigot and be delivered through it. e current mixes with the water beneath, and, of the increased volume of l, only a small part can overflow. The remainder passes down, and consand passing out of the spigot. Hence, though spitzkasten products are aximum size of grain, from coarse maximum grains in the first to fine s in the last box, the particles in each spigot product range from its maxfinest slime. The operation is therefore much less perfect than that of ifiers. Operation of pointed-box classifiers can be improved by addiplate parallel to discharge side of box, and rising above water level, thus lined rectangular sorting column. Additional, submerged baffle-plates this space occupied by the rising current, not only to assist further in he effect of eddy currents, but to increase settling capacity, since grains e low-velocity stratum adjacent to the upper side of every baffle plate d more rapidly to bottom of box.

ifiers (sand-slime separators). Three designs are in common use, s oscillating rakes which pull the sand from receiving tank up an scharge it at the top above water level, while the slime overflows of receiving tank. ARGALL classifier has 2 screw conveyors for sand up the incline and delivering it above water level, the slime s in the Dorr. In the ESPERANZA-FEDERAL, 2 parallel sprocket crapers draw the material upward. All these effect good sepae from sand, and deliver the sand with very little water. The er used is a little spray near top of incline, to take out as much of slime as possible.

e de-slimer and de-waterer (Fig 51). An ordinary settling box ottom may be about 5 ft wide by 12 ft long, with sides sloping orizontal. The 8-ft ering cone, with 60° m overflow 25 ft in . Thus, the width the cone is 5 times inted box, and, for of feed, the depth f overflow is ⅛ as he maximum grain ill be about ⅛ as the pointed box. the cone to settle fore much greater. the pointed box is with a plunging follows rapidly m, and stirs up the settled; a disadvannt in the cone (58).

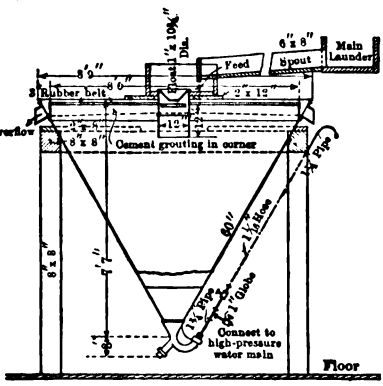

Fig 51. Callow Settling Cone (58)

f Callow cone. The cone is a whole-current classifier, in which the y constant throughout, though unavoidably somewhat stronger at cirn near center. Feed enters at center through a vertical pipe, which has subdue force of current; it then spreads and rises, all particles that can ivered to the spigot, the remainder going to the overflow. It follows ished quantity of feed, or with a larger cone, the size of maximum g-

STANFORD LIBRARIES

in the overflow will be smaller. The apparatus With a smaller cone, or a larger quantity of pulp DE-SLIMING CONE. Hence, by deciding on the size drawn, between clear water and slime, the size of give clear water are determined. In other words, can be allowed to go into the clear water and still

Callow de-watering cone. A pulp feed of water clear enough to discard or to use again of pulp would differ according to the value o ample, in treating galena (with lead at 4¢ per lowed in the clear water, than if treating tellu per oz). Again, settling is hindered by extre mill in winter, clear water can never be obtain be helped by saline solutions. In Arizona, wi even when this has been precipitated by addi in the water helps rapid settling.

Table 56 has been prepared to aid in deciding pulp needed in a given case. Thus, for an 8-ft d feed, the velocity rising to overflow is 0.34 mm per se (Table 52) 0.022 mm maximum diameter. Table 5 is obtainable from a 7-ft cone and 20 gal per min, 5-ft cone and 10 gal per min feed. If the 8-ft con sired to lift 0.1 mm grain to overflow, the rising (from the table), the same work can be done with a 2-ft cone and 30 gal per min feed.

Caldecott cone (109), developed in connection a flat diaphragm supported by 4 lugs riveted to space between edge of diaphragm and wall of cone about 1 in. The cone is allowed to fill with sand t is adjusted to maintain sand at this level. Owing spigot opening can be large. Function of diaphra of sand and thus prevent outrushes or clogging at

ring boxes are used wherever the quantity of water accompanying too large to feed to the next concentrating machine. They are gular boxes, but hopper-shaped boxes are better if space permits. In the overflow is clean. If it carries too much value to discard, this urned to the mill circulation, at a point where the contained sand arm and the values may be saved.

rent box classifier, or settling tank, is one in which all the water moves ity from feed end to overflow. It requires a very systematic distributer at f the water plunges into the tank it may give a rapid bottom current, which ow and carries with it larger grains than it should. Sometimes there is a face current toward feed end. If properly adjusted, spigot products taken bottom will show same grading as a spitzkasten. Some prefer to use this ributer, with the last spigot product as nearly like the first as possible, in e plunging feed, quick bottom current, and absence of careful distribution s.

ontents of tank in gal C, and number gal fed per min F, then $C + F = T$, min pulp will take to pass through tank. Again, knowing depth D (in or 2 shows the diam of quartz grain which will settle D mm in T min, thus um size of grain in overflow. In discharging from bottom, the spigots di- locity and quantity of water overflowing, and also size of maximum grain. **tanks or reservoirs** are for settling sediment, so that the water can be re- circulation. Where reservoirs are used, they should be in duplicate, one receiv- r from mill and returning clear water, while the other is being cleaned out for a

20. Jigs, Types and Co

The work of jigs is based on action of alterna
rents of water, through a bed of sand resting on
or PULSION, causes the mixed grains to strati
settle in water under the conditions; the heavie
downward current, or SUCTION, causes the sm
pass down through the interstices between the
screen. Pulsion is the primary action, suction
of suction is advantageous for jigging mixed
disadvantageous for closely sized products. Ji
the coarser products, from 50 mm (2 in) to
products go to Wilfley tables and vanners.

-sieve **hand jig** (65) is used in preliminary testing work, or for small-scale ot warranting expensive plant. Fig 53 shows one form, consisting of a tank, spended a sieve frame. Screen is usually of cast iron, with slots about $\frac{1}{16}$ in ieve is moved up and down by hand by lever *D*, rod *O*, lever *E* and 2 rods is loosely connected to *E*, enabling operator to give an upward blow on *E*, n imparts a sharp down stroke to the sieve, causing it suddenly to leave the orted, which then falls through the water and effects the separation. Ma- arse as 25 mm (1 in), and as fine as 6.3 mm (0.25 in) is treated, but

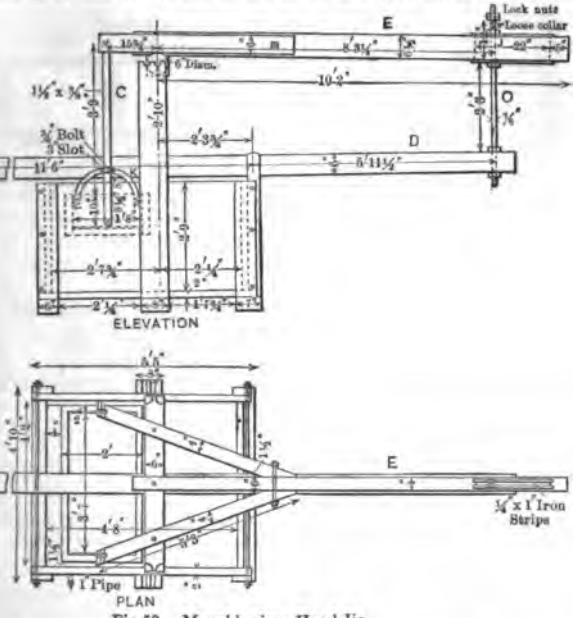

Fig 53. Movable-sieve Hand Jig

n stuff 12 mm (0.5 in) and below. It is fed by shovel to a depth of about level should be slightly above top of screen frame, insuring freer jigging. ite number of strokes (100 or more), the layers are skimmed with a short- The top layer may be tailing; the next, middling for recrushing; next, rich e re-fed with next lot; next (as at Joplin, Mo) may be clean sphalerite con- he smelter, and last layer on sieve may be galena. In Missouri, the last ide, and when a sufficient quantity is collected, is treated on a secondary jig, ean galena, the sphalerite top layer going back to primary jig. The hutch be re-treated on a similar jig with finer screen, but, as it is difficult to get result by hand jigging, the hutch product is sold to a sludge mill, which y power jig and tables. Each jig requires one man. Hand jig costs about constructed, and needs few repairs. It has the advantage over power jigs of tle water, but the disadvantage of small capacity. Rittinger gives capacity as 3 or 4 cu ft of ore per hr, for each sq ft of screen surface.

k vanning jig (65) has a tank or hutch 25 ft long, 4 ft 2 in wide, n deep (inside measurements).

le screen 2, submerged in water, is 20 ft long by 2 ft 8 in wide, divided of pockets by transverse strips, to retain the screen bedding in place. The

The **k of the last** 3 or 4 compartments goes to finishing jig for re-jigging.

met & Hecla mills, on conglomerate copper rock, two 5-compartment jigs **uct of one steam stamp**; 325 tons of sand below $\frac{3}{16}$ in, containing 45% of **24 hr. On Lake Superior amygdaloid rock**, three 5-compartment jigs treat **one steam stamp**, or 600 tons of sand below ¼ in, **with 40%** slime, per 24 hr. **er is driven by the sliding-block slow return on some of its compartments**, and **entric on others.**

charges. (*a*) **By skimming to remove concentrate.** To do this the **s are skimmed off first and afterwards returned.** (*b*) Shield and dam (Fig 57). Shield *E* reaches from above water level the screen. Only the bottom layer of concentrate can **ugh opening** *F* to the space behind the shield; then an **dam permits** concentrate to discharge (65). Height can be adjusted to prevent tailing from entering con-and height of dam to prevent concentrate passing out ng. **Height** of shield, and of dam above shield, are by trial. A simple computation will determine this **lly**, but the result is never attained because of vari-**rbing** forces. (*c*) Pipe and pan discharge (Fig 58) **blique pipe** *p*, passing from screen through side of **A pan**, hinged beneath it, can be raised or depressed **nb screw** on a bolt. This is not so automatic as *b*, but has succeeded **laces** (62). (*d*) Harris air-vent discharge is especially good for drawing from whole width of the tail of a screen. (*e*) Searing rocking pan and **harge** is an improvement on pipe and pan, where eddy currents around the pipe may harm the jigging. It can discharge large quantities, where the concentrate exceeds 50% of the feed. No other discharge is reliable in such case. (*f*) Shields' scoop discharge (71) lifts all concentrate above a certain adjustable level. As the concentrate can never be drawn below that level, and as very little water is discharged with it, this is probably the most per-tomatic discharge known. Monteponi discharge (Fig 59) is a pipe, ½ to **n**, according to coarseness of ore, set at a slight slope, and perpendicular **n** of jig compartment. Discharge is usually intermittent for fine ore.

ht of jig tail-board. A common height for medium sizes is 4 in; for es, 3 in; if the heavy mineral has high specific gravity, even 2.5 in. y coarse material, it is probable that 6 in, 8 in, or even 10 in may be For example, for 2-in lump (50.8 mm) with shield and dam discharge, ould be 3 in above the screen to let lumps through. Hence there should 5 in of gangue over the 3 in of concentrate to protect it from loss. This equire a dam 8 or 10 in high. These figures are not fully proved, the Cananea bull (roughing) jig has 8-in tail dam, and elsewhere coarse been jigged with a bed 12 to 18 in deep.

th and number of strokes. Stroke ranges from 2 in or more for very naterial, down to ¼ or ⅛ in for fine products. The chief point is to lift d sufficiently from the sieve to allow the particles to rearrange them- the water. The strokes per minute vary from about 100 to 250, the number with the longer stroke, and vice versa.

tity of water is very variable, according to whether the jig is run on minimum d maximum feed. Dudley (93) proved that a free-flowing spigot requires as 3 lb water to 1 lb sand. If sand has a specific gravity of 3, there would be 9 water to 1 volume sand. If this is also true of the jigging bed, 3 tons water to nd are required on each screen, and 3 tons water to 1 ton sand in each spigot. f the spigot products are ⅓ of the feed in each compartment, a 1-compartment ting 100 tons sand, would use 330 tons water; a 2-compartment jig, 627 tons; rtment, 894 tons; 4-compartment, 1 135 tons of water. No satisfactory data ubject are at hand.

bed. Writer believes depth of 0.25 in is as much as should be al- is would be 12 grains deep, with 1/50-in (0.5-mm) pulp. Often a 5 to 0.2 in is preferred. Where the bed is 0.5 to 0.75 in deep, as ls, the settling is less perfect, and tailing is too rich.

ct from stamp mill is customary, the pulp passing through a copper ax to catch amalgam. If feed is from classifier, the classification good that no slime comes from spigots; then the first spigot and its h nearly half the values, but it may make tailing too rich to discard. igots and vanners yield little concentrate, but make very low tail- verflow slime is ready to go to canvas, or any other approved table. olates the two difficult products, first-vanner tailing and final slime, ordinary method leaves them mixed with the clean tailing of the later vanners.

Isbel vanners are side-shake machines, which have been more used, es- True, than any others. They make clean concentrate, due mainly to the wash-water jets (Fig 66) which efficiently wash away the quartz. On the he side-shake is apt to cause banks on each side of belt, which may be 2 or d may cause loss of values. The Isbel is a new vanner introduced by Utah and said to do good work. Its shaking frame is supported by leaf springs, Shepard and Searing, which maintain a perfectly rectilinear motion.

or suspended vanner, has a rocking or side-shake motion, due to 4 sus- which slope inwards and downwards towards the belt on both sides. The at and moved from one side, while it is depressed and moved towards e, the motion being reversed on return stroke. A distinct advantage is the de banks (sand corners) resulting from this peculiar motion.

Embrey, and Gates vanners have end shake, which produces cleaner tail- clean concentrate than the side shake. There is little tendency to form side se the flange does not interfere with the vibration of the pulp. This makes ailing, but the endwise swing of the wash water does not remove the last of rom the concentrate so well as the side shake. The Gates has a 3-ft belt, ope, rapid, short vibrations, and is used only on very fine pulp. The tailing and has to be re-treated on canvas tables.

28. Flotation Processes

Flotation processes of concentration (87) are based upon the reaction of ıar forces: surface tension (of liquids), and adhesion (of liquids and gases ıd of liquids on gases). Surface tension is the force which causes a slightly to float on water. The degree of adhesion varies with different substances. presence of gas and water, or oil and water, show stronger adhesion to the oil to water. If oil and gas are both present, since oil itself has strong adhesion bble, the adhesion of sulphide to water is further diminished. The behavior inerals is the reverse; they show stronger adhesion to water than to oil or tendency which is increased by slightly acidifying the water. The attach- as bubble to a sulphide particle causes the sulphide to rise and float. These nomena, aided by mechanical apparatus, separate the sulphide from gangue e sulphide floating on the surface, the gangue settling.

on. Following minerals may be separated from their gangue: molybdenite, ena, mixed zinc-lead sulphides, chalcocite, sphalerite, pyrite, chalcopyrite, phite, tetrahedrite, argentite, cinnabar, tellurides, sulphur, and metallic and copper.

ns. Oxide and carbonate minerals have not yet been floated extensively, y closely resemble gangue minerals in adhesive properties. FILMING with h subsequent flotation of the minerals thereby coated with an artificial sul- been experimentally successful at the Magma mill, Ariz (A I M E, *Bull* 122). ontain minerals which tend to float naturally, yet are undesirable in the con- uorite, occurring with certain zinc ores, floats with the zinc concentrate, and enalized by smelters. Certain mixed sulphide ores of Scandinavia contain , which readily floats, and so impoverishes the concentrate that it is unmar- n ore in which all or part of the sulphides is bornite or chalcocite sometimes e; possibly when these occur as secondary minerals.

elprat process (87). The ore, ground to 40-mesh, is charged into V-shaped, ats. A 2 to 3% solution of H_2SO_4, or acid salt cake, preferably at a temp of roduced through pipes which reach to bottom of vat, and so aid in mixing ore n. The acid attacks the carbonates, liberating CO_2 gas bubbles; these attach o sulphide particles, which form a froth, and pass off at overflow. The gangue, by the selective action of gas bubbles, goes through a spigot in tank bottom.

process. Ore is crushed to 40 mesh, de-slimed, and agitated with cold acid 0.19 strength, in proportion of 4 or 5 parts of solution to one of ore. Me- de scum is removed, the acid solution drawn off, and the pulp agitated with to remove any remaining acid. High-speed agitation appears necessary to urfaces of the mineral particles. The cleaned material is next run into the where it is thoroughly agitated with water and oil. The oil is 1 part castor rts low-grade kerosene; charge, 2 to 3 lb oil per ton of ore, some chlorine gas d. The oiled pulp is then elevated by compressed air, and fed to the top of cone *E*, Fig 68. Pulp runs down over the corruga- ulphides floating on surface of water at *B* and over- o launder *C*. Gangue sinks and is drawn off at *D*. thoroughly all the sulphides, the gangue product ust be re-treated 2 or 3 times on similar cones and e sulphide particles are thoroughly aerated in the g, oiling, and elevating with compressed air, and eadily take up air films and float at *B*. This process fully treated ores carrying 5 to 6% carbonates, and high saving, probably due to feeding a pulp entirely lime. Capacity of cones is small, and plant covers a Initial cost is higher than for any other flotation oover gives it as about $500 per ton daily capacity, of 1 800 tons per day erected in Broken Hill district.

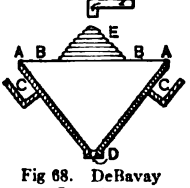

Fig 68. DeBavay Cone (87)

vacuum flotation process is also based on the selective action of oil for sul- r gangue minerals. Furthermore, if a solution of oiled pulp, sometimes con- d. be subjected to reduced pressure, bubbles of air or gas dissolved in water d, attach themselves to the sulphide particles, and increasing in size float to with the attached sulphides.

DRY CONCENT

29. Magnetic and Electros

Applications. Magnetic separation is em strongly magnetic iron ores, as magnetite, b minerals. The separation of sphalerite from p nary roasting to convert non-magnetic ore in Other instances are: separation of franklini lemite, calamine, and calcite; tungsten from chalcopyrite; rutile from apatite; rutile, ga other; garnet from garnetiferous rock; ga minerals from corundum; siderite from cryol from gangue; hornblende from valuable m chromite from other heavy minerals. Sizin when minerals have nearly the same magn be fine enough to set free all the values. magnets see Richards' "Ore Dressing," p 790.

Cost of magnetic separation comprises needed, attendance, repairs, and electric cur the separation is easy or difficult. With a goo separation alone, not including the preparatio 25¢ per ton. The total cost, including prepa should not exceed 50 to 75¢ per ton.

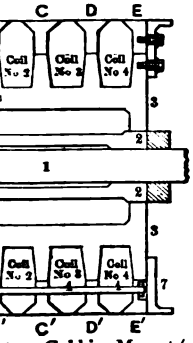
Types. (a) Magnetic separators of primary n poles causing the separation are energized direc Cobbing magnets, and Wetherill and Ball-Norton of secondary type, in which the separating magnet primary magnetic field in which they lie. Exampl Knowles, and Gröndal separators.

Cobbing magnets may be used to remov present in ordinary crude ore, before the ore magnets are suspended over a belt conveyor a off by hand at intervals. Their usual functio waste before fine crushing, thus saving cost o be run wet or dry.

Firmstone magnet (Fig 71) consists of a cylind shaft. The drum comprises: shaft 1; magnet co guttapercha ball 5, pierced to make a water-tigh

king a water-tight joint; brass rings 7; and *AA'*, *BB'*, *CC'*, *DD'*, and *EE'*, onstituting magnetic poles. Coils 1 to 4 are so wound that *AA'*, *BB'*, etc. ely north and south magnetic poles. When running dry, the material is y a conveyor belt, and carried off by a belt running on drum itself at right veyor belt. When running wet, the magnetic drum, which is water-tight, x. The water which brings in the pulp washes away the tailings, while the s removed by a belt. Other cobbing magnets are those of the Manhattan the Eastwood Improved Lifting, and the Bilharz Cobbing Magnet.

l magnet (Fig 72), made by Stearns-Roger Mfg Co, Denver, Colo, e of high magnetic intensity, for weakly-magnetic dry ores (77).



stone Cobbing Magnet (77)

Ore is distributed from feed hopper, evenly across a wide conveyor belt, which passes between upper and lower magnetic poles *aa* and *bb*. Poles of upper magnets *a* are wedge-shaped, to concentrate the magnetic force, those of lower magnets *b* being flat with rounded edges. Magnetic material jumps up-

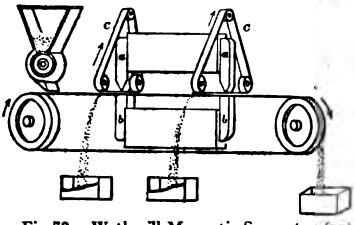


Fig 72. Wetherill Magnetic Separator (77)

stronger pole, the cross belts *cc* preventing the material from adhering to d carrying it out of the field. This machine has 1, 2, or 3 double magnets, d with a rheostat for regulating strength of current. Table 67 shows work machine on ore of different sizes, and illustrates separation of minerals of gnetic strengths on one machine.

width of CONVEYOR BELT of Wetherill separator for treating weakly- res is 18 in. The narrower the belt, the less electrical energy is re- emove a mineral of same magnetic susceptibility. Proper thickness 0.125 in for very weakly-magnetic minerals, 0.25 in for medium, and r strongly-magnetic minerals. In practice the standard machines n belt. When minerals of stronger magnetic power are to be removed e of weaker magnetic power, the poles of first magnet may be lowered, o of brass 0.125 in thick placed between it and the belt. Proper elt must be determined for each ore. The TAKE-OFF is an endless ride, and 1/32 in uniform thickness. Its speed should be such as to lear of the conveyor belt, and it depends also upon quantity of ore Proper DISTANCE APART of the MAGNETS must be determined by aries from 0.5 in on weakly-magnetic ores, to 1.5 in on strongly These adjustments govern size of feed; for weakly-magnetic ores ger than 0.03 in seems advisable; for medium-magnetic, nothing 0.25 in; for highly-magnetic ore, nothing larger than 0.375 in. L ENERGY required by No 3 machine having 3 double magnets, with 000 and 100 000 ampere-turns, respectively, is 50 amperes at 125 .4 hp. MECHANICAL ENERGY depends on speed, and varies from 0.5 WEAR AND TEAR is almost nil. Take-off belts, practically the only newal, last 1 to 12 months, and cost $1 to $2 each. Two men can to 16 machines.

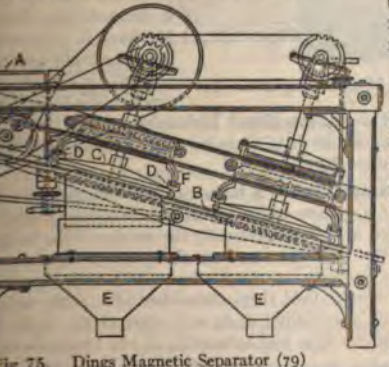
gnetic separator, type "MM," is especially designed for treating ores o a low magnetic intensity. It can make in one operation 5 products, viz: non-magnetic material and 4 grades of magnetic product (78).



ig 75. Dings Magnetic Separator (79)

Ore is fed from hopper *A* (Fig 75) to a vibrating conveyor *B*, over which it passes in a thin layer through 4 zones of separation, covered by the rims of rotating disks *CC*, carrying secondary magnets *DD*. The latter attract and carry away the magnetic material, discharging it over the sides of the conveyor into hoppers *EE* for final delivery. Magnets *DD* are saturated, while over the conveyor, by the pole pieces *FF*, of mary electromagnets, but are automatically demagnetized as they pass out of c circuit to the neutral position, where rims of the wheels overhang the conerfect and natural discharge is thus given on both sides of conveyor, resulting

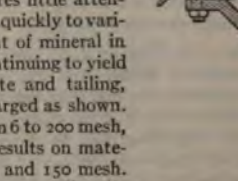
tent pulsations of air, admitted
through rotary valve *R*. It is
stratified on the screen *S*, the
heavier particles *B* going to the
bottom and the gangue *A* to the
top. The operation is auto-
matic and, once the feed is
regulated, requires little atten-
tion, responding quickly to vari-
ations in amount of mineral in
the feed, and continuing to yield
clean concentrate and tailing,
which are discharged as shown.
It treats ore from 6 to 200 mesh,
but gives best results on mate-
rial between 12 and 150 mesh.
Close sizing is not ordinarily
required. All sizes of the jig
have same cross section, 3½ in,
but vary in width. The smaller
size, with screen surface 3½ by 24 in, weighs
has capacity of 4 to 10 tons per 24 hr. T
36 in, weighs 300 lb, costs $450, and has



Fi

STANFORD LIBRARIES

, 40 to 50 lb at the rotary valve. For the air supply, about 0.5 hp er ton per day.

Steele & Steele dry concentrating table (86) resembles the e in its tilting frame and head motion. Fig 80 is a diagram (79) ion of top, in which *A* and *B* are impervious , *D* pervious cloth, and *C* supporting ribs. trips are narrow, tapering, and terminate gonal line. Above is the layer of pervious , and from below rises the air current, at re per sq in. The sand is stratified on the per strips having an effect similar to the ilfley table. The head motion propels the ns toward the concentrate end, while the s roll down the slope. Dust must be removed and ore closely sized nent. Sizes treated range from 4 to 200 mesh. For the finest mate- ers state the capacity as 1 000 lb per hr; for 8 to 10 mesh, up to 6 000 lb e table deck is 5 by 12 ft; weight complete, 2 500 lb; power required, e fan requires from 0.5 hp for slimes, to 6 hp for 8-mesh material.

Fig 80. Diagram of Sutton, Steele & Steele Pneumatic Concentrator

ater for concentration. The advantages of air over water as a g medium are: water not everywhere available, no trouble from ducts are dry and ready to ship. Disadvantages: fine crushing is vith resultant fines and dust; preliminary drying is expensive; tween close limits usually required; minerals of nearly same sp gr lt to separate than by water concentration; clayey matter can not ated nor soluble salts dissolved.

ACCESSORY APPARATUS

31. Samplers and Sampling

; is required to determine value of crude ore, tailing, concentrate, other product, at different stages of concentration.

f ore taken for a sample depends upon size of grain, and character of ore as and occurrence of values; whether rich and "spotted," or well disseminated. densed from Richards' "Ore Dressing," p 852, gives ratios between weight l size of largest permissible grain, for different ores. The first requisite for mpling is that the sample and "reject" shall be uniform in composition at he process of division. After each "cutting down" of sample, the ore should er, and mixed before next cutting.

Maximum Size of Crushed Ore Particles Permissible in Sample

Low-grade and uniform ores		Medium ores		Rich and spotted ores	
mm	mm	mm	mm	mm	mm
200	100	75	50	30	5
65	35	24	16	10	1.7
20	10	7.5	5	3	0.5
6.5	3.5	2.5	1.5	1	0.15
2	1	0.75	0.5	0.3	0.05
0.6	0.3	0.25	0.15	0.1	0.02
0.3	0.15	0.12	0.07	0.05	0.01

e column under each class of ore implies a distinction into two varieties as. The second column of the table applies to ore that is very low-grade while the last applies to very rich and unusually spotted ore.

5. Revolving Distributer

Distributers are used to divide a stream of ore evenly between two or more machines (mill distribution), or to distribute ore uniformly to a single machine (machine distribution). Any mode of distributing ore by taking part of the stream all the time, as by drawing consecutive spouts from a launder, gives uneven products. An exception to this is the overflow of tanks, provided the same depth at all points. Gates distributer (Fig 37) divides a tank as many spouts as are needed, of equal width and depth. They

nachines or groups of machines. As a rule, where two or more similar machines or a certain amount of work, it is better to arrange them in parallel than in series. nachines in couples, one to make clean concentrate, the other, clean tailing, is in practice.

ng of concentrate. After being unwatered, or settled and dried, ate should be delivered to railroad cars, or other shipping conveyance, nically as possible. It may go by wheelbarrows direct to R R cars, rrows or conveying belts to bins, and thence to the cars. Barrels or used only for small lots, or for rich ore to guard against losses, or nsiderable handling in transit must occur. It should be remembered tonnage of concentrate to be shipped is a small proportion of the tonrude ore entering a mill; hence, it is not economical to add to mill height or the sake of discharging concentrates by gravity.

sal of tailing. A mill site should provide for ample room for tailing ommensurate with probable life of mill. When necessary to reuse the iling goes to settling tanks. If there be insufficient fall for tailing to pass vity it is elevated by bucket elevators or sand wheels (Art 33). Storing for possible re-treatment should be considered.

STANFORD LIBRARIES

Percentage of extraction depends upon: easily separated from gangue give higher percer of ore. Percentage of extraction usually increa rich ore justifies higher treatment cost, and it to nearly the same value as that from a poor c profit is the most important factor. The limit o limit, and concentration should be elaborated a yield a profit over working cost. (*d*) Purity of concentrate, the greater the loss in tailing; the value of high-grade concentrate more than offset

Tendency for the future is toward graded graded washing. General rule is to save the co but to crush tailing considerably finer before c sizes, 1 to 2 in, diminishes slimes and cost of cru is important; they are difficult to treat, and ge of the losses. Graded crushing, sizing, and jigg their losses. Slimes, whenever formed, should b coarser material, and treated independently. F Wilfley tables and in fine jigging; it may be gr good classification. Middling in the coarser size to free included grains; in the smaller sizes, spe sary, as the valuable minerals are apt to be flat separate from the more compact gangue. The towards saving the finest and most difficult value after the coarser parts have been saved by ordi

Cost at which profit vanishes. It is important t furnished with tables, showing the fixed charges, for net smelter returns for the different metals, at differ charges, and the milling cost and cost of production f point at which a certain grade of ore will fail to return

Accounts and reports. Careful cost records sho subdivided, to show periodically (say once a month) venient comparison, accounts should be based on a 2 000 lb. These records may be of three kinds: (*a*) A item (labor, supplies, etc); (*b*) Distribution of expens of the work, to determine what proportion of the tota tribution of expense and income among the various certain lots are being treated at a loss, which cuts d costs may be divided under the four general headings costs, losses, amortization of plant. To the milling mining, smelting, refining, marketing, and general ex special features, calling for modifications of the cost s

37. Laboratory Testing

(See also Sec 31)

Testing may be: to determine a suitable proc termine the general efficiency of a concentrating

Testing small lots is done by certain sma similar to those of full-size machines. For ex makes a ROLL-JAW BREAKER, suitable for crus Allis-Chalmers Co makes CRUSHING ROLLS and F Thayer's small portable STAMP MILL is made by cisco. A nest of small circular hand SCREENS, (sieve ratio of $\sqrt{2}$), is invaluable for screen te

l, Ohio. For CLASSIFIER tests, the author uses a 12-spigot hindered lassifier, because of advantage of hindered settling over free settling. GING small lots, a hand jig with sieve box 1 ft square inside is most it. Round wooden screens are also suitable. Henry A. Vezin, Denver, ned a jig with sieve 3 by 4 in, which may be driven either by hand or . A small WILFLEY TABLE, with net working area 26 by 50 in, equipped regular Wilfley table mechanism, gives good results on small lots. anners and canvas tables can also be used for testing the concentrating of small lots of ores. The Cornish VANNING SHOVEL is used to sepa- y and light minerals, for products 3 or 4 mm diam down to slimes, st satisfactory on material finer than 1 mm coming from jigs, tables, ers. Enameled vanning plaques are very convenient.

ests for FLOTATION can be made by mixing the fine ore, oil, acid, and king in a closed jar, then allowing tailing to settle. The oil is poured ne added to dissolve the oil from the sulphides and the mixture heated , thus precipitating the sulphides. Or, the tailing can be dried and ecovery being computed by difference.

l 2-pole MAGNET may be made with sharp-edged pole pieces. This ed with weak current to test the applicability of the Ball-Norton con- and with strong current for the Wetherill.

amation tests for gold on small lots may be made in a "gold pan," the crushed ore with water, adding a few drops of mercury and thor- itating for a considerable time. A good amalgamating test for gold de on 1 kg of ore in a 2-gal bottle, revolved end over end with 50 grm amalgam. Most of the rusty gold will be caught. Pan amalgama- ilver may be done by charging the ore, crushed to pass a 40-mesh a small cast-iron amalgamating pan, supported on iron legs to per- cation of heat beneath, and provided with a grinder which should om 120 to 150 rev per min. The pan may be run with different reagents ring results.

g a given ore, analyses should be made of different representative samples, to composition and association of the different minerals. For instance, in ore silver, lead, pyrite, blende, and quartz, the percentage of silver carried by nt minerals should be determined. The mode of occurrence of the ore with , whether finely disseminated or in masses, is important in deciding amount of ecessary to free the mineral. Sizing and hand-picking tests are most valuable, r classifying, jigging, and table tests. Sizing tests and assays of the different ould always be made, to determine percentage of values saved and in what h ore will present different problems, and the ore dresser must use his judg- ciding what tests promise the most information. At present, many companies g distinct processes, for example, the Elmore Oil Process Co, will test a small lot heir particular process and report the results without charge, or for a small fee.

n regular mill work are made by determining, for each day, the weight e of the crude ore treated, together with weight and value of con- nd tailing. The work of different machines is tested by sizing tests, yses of the different products, and their weights.

38. Mill Flow Sheets

flow sheets which follow have been selected with the view of present- reatest variety of concentration and of method. In some instances, complexity of diagram, elevators, centrifugal pumps, conveyors, de- etc, have been omitted; for, while they are indispensable, they play n the actual separation of values from waste, though they often do disposal of both values and waste.

2. Remarks on Sampling Methods

l. Ore is sampled by hand or mechanical methods. HAND METHODS, and simplest, require merely shovel and wheelbarrow. They are to all ores; and are preferable, usually necessary, with wet or sticky MECHANICAL METHODS, stationary or moving devices in the stream of atically divert the desired proportion for the sample. Though first cost enance of a mechanical plant are important items, its operation may be s and the preliminary sample obtained a few minutes after unloading; e ore is less important and probably unnecessary; and, when correctly d and operated, liability to error is much less than with hand methods. a mechanical plant may be so constructed that a correct sample is , thorough inspection always discloses any such condition.

nical devices are of 2 kinds; stationary, which continuously divert cerons of the stream for the sample; moving, which periodically divert the am for the sample. They respectively take part of the stream all the all the stream part of the time. Theoretically and actually, stationary dependable as moving devices. Ore does not flow uniformly, but is of many streams of varying proportions of fine and coarse. Thus, corll shells permit passage of coarse particles at certain points, and in an r angled chute, or barrel-mixer, the finer will seek the lower points. one or more compartments of a stationary device may steadily receive proportion of coarse or fine. With properly constructed moving devices, ross the entire stream, the manner of delivery is unimportant, even if s previously sized, because the sample spout is under all sections of for equal periods of revolution or oscillation.

nary and final sample. Whether sampling is continuous, from ing to final grinding, or is a series of unrelated processes, the operataining the preliminary sample from wet original ore is distinct from

STANFORD LIBRARIES

side, while the finer drops vertically. A small accumulated error after passing 3 riffles. This of the riffles across the stream; but to be effe mechanically and not left to the workman's wh small divisions to clog, the device is applicab

These are so constructed and operated th of rotation or oscillation a division called t stream for the sample.

Snyder sampler. This type (Fig 3) cons ing in a vertical plane on axis *B*, with an inclin it. As the spout passes the sample such proportio circle of revolution. At and is thrown back into

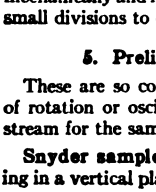

Fig 3. Snyder Sampler

These machines being of c parts, and are accessible at samples per min are taken, ting with 2 or more spouts. angles to the plate and in plan Thus, as the edges wear, the usual inclined delivery chute As the device revolves in a plate for half a revolution or from spout to the reject.

Vezin sampler is used quite generally and ods of sampling. There are many varieties Fig 4. Vertical shaft *C*, revolving with the rev per min, carries sampler spouts *AA* under *B*, and diverts sample to center and through s tom. During remainder of revolution the o reject receptacle.

ADVANTAGES: can be made accessible for cleaning during sampling; frequency or proportion of sample number or angular width of spouts; 2 intermeshin be operated for taking duplicate samples. DISA quires much head room; damp ore collects in or ma spout; the long upper edges of spouts quickly becon and worn. It is not patented and there are no restri facture or use, though the inventor, H. A. Vezin, s for a correct sample. He insisted that sides of san

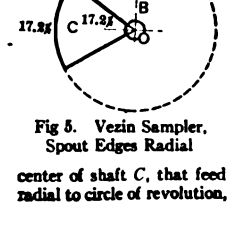

Fig 5. Vezin Sampler, Spout Edges Radial

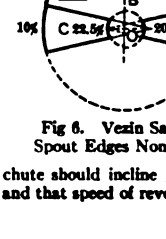

Fig 6. Vezin Sa Spout Edges Non

center of shaft *C*, that feed chute should incline radial to circle of revolution, and that speed of rev

dges, to lessen liability of particles to jump from or into sample spout. CHIEF ERROR is the position of sample-spout cutting edges, due to faulty construction, of non-radial sides. A variation from radial positions, imperceptible with machine in motion and proved only by measurements, may cause appreciable error. This is shown in Fig 5, 6, and 7, which are horiz views of Vezin samplers in actual use. Fig 8 is from a photograph of a machine just before installation. If segregating delivery chute is added, the error may be anything desired, as shown in Fig 9 (7). In the cuts: *B* is inside line of spout at center of carrying shaft; *C*, top of sample spout; *O*, outside edge of inclined chute delivering ore to sampler; and the proportion taken for sample at points indicated. Fig 5 shows all cutting edges of spout radial, with equal arcs cut on *A* and *B*, and is the only correct sample regardless of segregation in the ore stream.

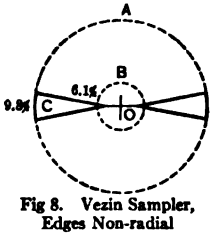

Fig 8. Vezin Sampler, Edges Non-radial

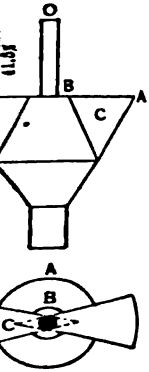
Angle between spout edges is too acute in Fig 6, 9, and too obtuse in Fig 5. Percentages (%) show proportion taken for sample at inside and outside limits of sample spout, and also at extreme points on delivery chute. Even such machines might not cause commercial errors except for use of the inclined, and more especially the knee-joint chute (Fig 9). By adjusting the angle between *D* and *D'*, and varying their lengths, control of distribution of coarse and fine is possible, as proved by samples taken across the chute. The chute shown in Fig 9 would probably cause a low sample in Fig 6, 9, and a high sample in Fig 7, 8.



e-joint Chute, with l Vezin Sampler

There are many modifications of spout and chute that will cause this otherwise excellent machine to deliver an inaccurate sample. Previous to year 1900, machines were found with sample spouts intentionally leaky, causing loss of fines; delivery chutes dropped fines just beyond outer circumference of spouts; and sample spouts were made with parallel instead of radial edges, with ore feeding from outer circumference toward the center, and producing samples of 60% or less of the actual gold value. Since 1900, similar but more refined practices have been devised, so that it is wise always to inspect carefully every installation. The machine is generally conceded to work accurately if the spout edges are constantly radial and feeding chute is vertical and at proper distance above the spout.

Chas. Snyder sampler is in principle similar to the Vezin, in that it revolves in a horiz plane and has h radial edges (see Fig 10, lettered like Fig 6). It has a special annular, livery chute, covering an arc of 90° directly over the sample spout, and narrower at top where it receives ore from ele- ls, or shaking trays. Within this spout are a short horiz iron rods, to scatter and delay the and destroy any previous segregation. The as 4 sample spouts, assuring continuous flow em, instead of the intermittent flow of other Errors of construction noted under Vezin sam- , but in less degree because of narrowness of uts.

plates are steel boxes through which steam s, having a top drying area of 6 to 20 sq ft, h the sample is spread. Steam coils are in a brick or steel closet, the pipes forming or holding pans containing sample. Electric nsist of resistance coils in a closet containing or holding sample in pans. Temperature is nt and should be slightly above the boiling point corresponding to elevation above . Thermometers are used for steam, and automatic regulating devices for electric Insufficient or excessive drying causes trouble and error in assaying and valuation e (Art 7).

ding of the dried sample to 40 to 60 mesh is done by rolls, or grinders Englebach cone- or Braun disk-type. The ENGLEBACH TYPE consists of shaped cone, revolving horizontally within and beneath a stationary g flaring at top and bottom. The cone rests on a vertical driving shaft, e ring is carried on a hinged frame so that parts are quickly swung open ning. 8 or more channels are cut vertically in the grinding surfaces of one and ring. Ore is fed through top of ring and channels. Fineness of g is controlled by regulating closeness of contact between cone and ring by sting screw and lever attached to driving shaft. BRAUN DISK-TYPE consists cular iron plate, revolving in a vertical plane with its face in contact with e of a similar stationary plate, hinged at the bottom to permit separating aning grinding surfaces. 6 or more feeding channels are cut in faces of lates, beginning about 1 in from circumference and deepening at center. fed into a hopper passing through center of the stationary plate. An ng screw on shaft carrying the revolving plate regulates pressure between tes and consequent fineness of grinding.

lity of iron used in grinders is important. If hard it soon polishes and fficiency; if soft it may lose enough iron to the sample to lower the value iably, or may even take up particles of valuable metals from one sample op them into a succeeding sample. Imperfect parts must be promptly led; filling cavities with babbitt is not permissible, as metals are removed he sample by the soft filling. The ground sample may be further reduced, ed, by methods described above.

ening is done through sieves varying from 80 mesh for low-grade to sh for highest-grade gold ores, average being 100 and 120 mesh (Sec 30).

s should be free from missed wires and holes, and so constructed that all solder- on the outside. Sieves with broken or misplaced wires should be promptly dis- and not repaired with a drop of soft solder which may gather metals from the While it is not desirable, it is accepted custom to use loose iron washers in the prevent balling of dried sample and to hasten screening. Some plants even use tion a stiff paint brush. If hastening is overdone, especially near end of process, res of copper, gold, or silver may pass through and cause puzzling differences in g. Single wires of gold have been found heavy enough to cause 0.5 oz gold ce in check assays (7). With such ores, washers should be discarded and more ken to grind the pieces of metal. Oversize from the sieve is either reground or l on the bucking board (Sec 30, Art 1). Quality of iron in bucking board and r is important (see above).

STANFORD LIBRARIES

Metallic particles resisting grinding, and ore (or copper caps or iron from the machine assayed (Sec 30, Art 3).

Mixing the ground sample, now called PU ing into a rapidly revolving gold pan, by turni ing through an Anaconda Mixer, or by rolling paper or oil cloth (Sec 25, Art 4). Dividing by coning and quartering, by the spatula, by or preferably by riffling (Sec 30, Art 1, 3). P are used for holding this assay pulp.

7. Moisture San

Moisture samples. Ordinarily 2 to 4 sam from each carload, while high-grade lots ma may gain or lose water rapidly, moisture samp to the time of weighing the lot. In case of gr obtain proper proportions of all sizes, as fines u than coarse pieces.

As individual grab moisture samples may vary a an average. To avoid this difficulty samples may b chanical device, during or after the sampling and w smaller. As ore becomes drier during sampling, it i 10% to the moisture as determined from the crush mospheric humidity. While all modes of determini mations, the sample taken after crushing is preferab

Weighing the wet sample requires care a use of either the finest or the coarsest materia ing should be avoided. Special scales, for show percentage loss without calculation. Sa drier and at same temperature used for assay differences in moisture or in roasting of oxidiza can not be accurately computed.

8. Multi-samp

Check sampling. Custom plants usually settlement is agreed upon. Owing to limited bed or store the bulk of a lot, retaining intact and usually only a few hundred pounds. Lo determine the amount so held, though the Sta ute for retention of 2.5%. It is the practice SAMPLES, called ORIGINAL and DUPLICATE, or ev the division being made when sample has been exposes gross errors in later work, detects salti resampling, and averages errors of faulty meth

At some plants anything less than a specified p of multi-samples makes settlement on the average co automatically calls for resample of the retained p 5 to 20%, usually 10%. Close checking of multi-s in the portions so handled, but does not prove corre On the other hand, large or constant differences indic methods, and make possible undesirable "jockying" 11). Many plants are so constructed and operated pling of any sized lot may be less than 2%, with on

9. Synchronism

ition. When two or more mechanically-operated sampling machines nged in series, there is a constantly recurring cycle in their relative . If one horizontally-revolving machine is directly beneath another ne rotative speed, the spouts will have a constant angular difference, n no intervention the second sample spout may be arranged to receive rt or none of the first sample. At different speeds one spout will pass r at regular intervals and, if not obstructed, the sample from the first will regularly strike certain points on the second machine in any

esired. Table 2, containing data from a large plant, illustrates this. ow figures S show number of consecutive samples from first machine partly or entirely into second sample spout. Lower row figures R mber of consecutive samples passing entirely into the reject of second . These should be read, S 5, R 5, S 10, R 1, S 1, R 5, and so on.

alue of any sample portion depends on at least part of it reaching the ultimate its complete loss being equivalent to omitting from the shipment the portion which it represents. Intervening rolls alone do not correct synchronism, but , the continuous delivery of the Chas. Snyder sampler, closed hoppers, barrel- nd shaking trays, lessen or prevent it. The BARREL-MIXER has the disadvan- egregating coarse material and corrugating the following rolls. The SHAKING ses ideal delivery, besides being a generally useful device. It delays the ore ly to prevent synchronism, gives uniform feed, can be made to correct uneven olls and to stop pieces of steel or hammer heads that might injure the machinery.

10. General Considerations

ghing. Small lots, or high-grade ores, are weighed on special bullion Carload lots are weighed on railroad scales, preferably housed and with etween platform and coping covered by old belting to prevent jambing es of ore. Railroad scales should be tested monthly by special test approx weight of the empty and loaded car, and daily or weekly by 40 ghts totaling 2 000 lb. Great care is necessary in checking with small ghts, as the 20-lb minimum error of the scale is equivalent to 2 000 lb a load of 100 000 lb.

hould be uncoupled and stationary when weighed, and time allowed for scale swing both up and down. Rapid balancing with rider slightly over and under- or gross and tare will cause 100 lb or more error in net weight. Balancing scales g fine ore or shot on rider may cause an error of several thousand lb. Wagon o short for both team and wagon, must have roadway at each end level with , and brakes and tugs must be loose during weighing.

mplete lots. Portions of a lot may be received at widely different necessitating the questionable practice of taking several preliminary to be combined later for the final sample. With mechanical methods to error is not serious, but with hand methods different sets of work- king slightly different proportions may cause errors never discover- o bedding of the bulk of the lot.

STANFORD LIBRARIES

A combination may be made of SAMPLING WITH ROA No 3), though this is of doubtful desirability. There excessive dust, and general lack of care when sampling

Cleaning. Plants should be reasonably tight ore chutes tightly enclosed to prevent the too In hand methods, cleaning with brush and broom mechanical mills, cleaning immediately follows proceed from first to last crushing and sampling through all following machinery to insure a pro

Many mills supplement brush and broom clean piped to convenient points. After the regular cleani are fed with barren rock or slag, and again cleaned It is good and economical practice to discard cones, diately after grinding a very high-grade ore.

Salting. Deliberate salting by addition of to salting at the mine (Sec 25, Art 9). Device have been quite elaborate, including high-gra necessary to cause the desired salting, and pro cies or for following a lot from sampler to sm for nearly a year, was largely responsible for known smelting company. Of greater impo machinery, producing either a high or low sam may employ trained men, called MOOCHERS, t sampling company may lock sample-hoppers important machines. eying with assays. Assays reported by the seller are usually higher
e buyer's, the relation persisting through reassays and resamples (Tables
6). On high-grade ores larger differences occur (Table 7). Eliminat-
deliberate falsifying of the mining camp telephone-system of compari-
gures, there still exists the jockeying with assays frequently found in
ing practice. Simplest example is the cupeling at an intentionally, but
inally, high or low temperature, giving correspondingly low or high
vith no particular strain on assayer's conscience.

incipal and more specious excuse for jockeying is the fact that assaying of ordi-
o is not an exact science. Due to conditions shown in Art 6 (Screening), the
scientious and skilful assayer may be unable to weigh from the pulp two or
rges containing exactly the same amount of gold or silver. Hence it is cus-
o assay from 3 to 12 separate charges from each pulp, to weigh all the buttons
and report the average assay only. But the large differences occasionally
between the buttons furnishes a plausible excuse for weighing them separately
rding, in the average, such as differ excessively from the majority. This elimi-
ay be done by the assayer, or by the settlement clerk, neither of whom may
responsibility. It is natural that judgments of buyer and seller will differ as
uttons should be rejected; but even a conscientious umpire is at a loss what to
nen buttons vary by several oz per ton. Possibilities for jockeying are greatly
when 2 to 4 multi-samples, with repeats, umpires, and resamples are made,
consideration of perhaps 160 separate buttons for one settlement.
r opportunity for jockeying is the relation between assays and treatment charges,
-called "splitting" points with assays. Assuming that an ore contains approx
per ton, and treatment charge is $3 if below 1 oz, and $4 if 1 oz or more, with
o per oz; the buyer prefers a final average of 1.00 to 1.045, and seller anything
5 to 0.955, each preferring the critical assays of 1.005 or 0.995 oz gold respec-
This is shown as follows:

045 oz	= $20.90	0.995 oz	= $19.90

Introduction. This subject is treated from t equipment and methods, with particular reference districts. Rare minerals, and some others of low assay or analysis requires special laboratory fa methods, see Fulton's "Manual of Fire Assayin Ore Analysis."

In a remote region, the question whether to tak the samples, will generally be decided by the nu factory fuel for fire assay, and distance from an e case, to secure reliable results, adequate equipme reduction of samples if transport of large sampl and, unless individual samples are reduced to sm that of assay equipment.

It is often important, in making mine examina results on certain samples, in order to resample in c sampling may be curtailed by advance informat samples is large, or the mine is in a remote distric ative, notwithstanding that it is rather bulky and assay work in the field is often beset with difficulti ment, simpler and more convenient methods of sought, but there is no satisfactory substitute for

e may be used for identification and qualitative tests (Sec 1); quantitative uire much practice and skill, and the results are unreliable. Further, fewer be made per day by blowpipe than by standard methods, and the work tious. An example will indicate the inherent shortcomings of the blowpipe Employing the usual charge of 100 mg for a 1-oz gold ore, 0.0034 mg of gold will

Combining results of 10 fusions gives only 0.034 mg, a quantity too small to dy measured without a microscope, and requiring a delicate balance for weigh- otal wt of ore used, 1 gm, is insufficient for a representative sample, and each d require 2 to 3 hours. The blowpipe is more applicable to high-grade silver ase metals. The so-called "pocket smelter" gives no more accurate results lowpipe.

seful for testing gold-bearing gravel, or pulverized gold ores, particularly those e base metals are oxidized. In experienced hands, it will give better results ores containing coarse gold than the ordinary assay on 0.5 A T (1 A T, or assay 6 gm) charges. (See Art 8; also, Sec 25, Art 7, Sec 31, Art 5.) The pan is re the gold is combined as telluride or is enclosed in sulphides, unless the sample ted.

1. Equipment

ng and grinding devices. If power is available, and samples are numerous, mechanical devices for reduction of sample should be used. e time and energy, and diminish tendency to excessively large cuts ore, which vitiate accuracy of sample. In selecting a JAW CRUSHER, strength, weight, and convenience in cleaning are important; for ores ack (due to moisture or talcy nature), a crusher with forced discharge le. For fine grinding, the DISK PULVERIZERS are efficient. There are akes; those having a stationary and a revolving disk give excellent hard and granular ores, though for talcy or heavy sulphide ores, they atisfactory. Ores of this class are better handled by a PLANETARY in which a revolving disk travels in an orbit, and discharge is positive. uction of coarse ore by manual labor the JAW CRUSHER is most efficient. small jaws and heavy flywheels of large diameter are necessary. a knack in operating these machines, slow feeding and high rotative ng essential. A simpler device is a STEEL PLATE AND HAMMER (cast ss very heavy, is apt to break), and a 3 or 4-in section of 10 or 12-in revent the pieces from flying; or, instead of the hammer, a "tamper" ler piece of pipe will be found more efficient. For added convenience, r may have a long handle, projecting through a hole in a board over- the pipe section screwed to a flange for sta- or fine grinding, nothing is better than BUCK- MULLER, which, to minimize salting of samples ust have a finished surface and be free from kboards with rim or flange on 3 sides have an surface. Some assayers substitute a piece of channel iron for the buckboard, using a muller roove. Mullers should not be over 4 in wide, ter bearing surface diminishing the unit crush- re. The Guanajuato Development Co has long buckboards and cobble-stone mullers, with usands of samples have been ground. They are a silicified rhyolite, and it is stated that the ited less than 0.5%. (See also Sec 25, Art 4.)

taking 6, 8, and 10 20-gm crucibles respectively. The ⅛ or ¼-in pipe ws usually furnished with these furnaces can be replaced with advan- small-bore copper tubing, known as hollow wire; it is easier to install nates numerous joints, with their liability to leakage.

ces. A cheap spring-balance, costing 15¢ to 25¢, with a pan suspended ngs, answers for weighing stock charges. PULP BALANCE should have ling at least 1 A T (assay ton = 29.166 gm), and should be capable of mounted and packed in the case drawer. They have either all-steel or steel knives and grooved agate bearing plates, the latter being prefer- r FINE BALANCE, following points should be considered. Since silver not require extreme accuracy in weighing, a very sensitive balance, always slow and liable to derangement, should not be chosen for this ne. Gold determinations are most exacting, and for a large number of , the balance should be of the best. The most sensitive balances are cate, and will not stand rough handling. The inverted or "no column" ecommended. Several makers have special portable balances, which but less satisfactory than the standard types, and should not be used anent equipment.

hts. For GOLD AND SILVER ASSAY, combination set of 0.01 to 100-gm o 4-A T "second grade" weights is advisable. The ASSAY TON (A T) as many milligrams as the avoirdupois ton contains troy ounces; there- g of gold or silver obtained from 1 A T represents 1 troy oz in 1 avoirdu- The short (2 000 lb) and long ton (2 240 lb) will be represented by an aining respectively 29 166 + mg (29.166 gm) and 32 666 + mg (32.666 EAD WEIGHTS comprise 1 mg to 1 gm, and should be of the highest grade. ights, as furnished by supply houses, are usually inaccurate and should . Slight discrepancies can be disregarded for silver weighings, but a e of 0.01 mg causes an error respectively of 20¢ on 1 A T, and 40¢ on harges of gold ore. ANALYTICAL WEIGHTS for base metal and miscella- terminations should include 5-mg to 100-gm first-grade weights. If ses of work are to be done, the 5-mg to 1-gm weights may be omitted analytical set. It would be possible also to eliminate the gram weights set, but this is inadvisable.

ore is weighed in METRIC TONS, gold and silver are reported in grams . As there are 1 000 kg in a metric ton and 1 000 mg in 1 gm, 1 mg silver obtained from 1 gm of ore will represent 1 kg per ton. Example: of ore gave 15.5 mg of silver and 0.35 mg of gold, the ore contains 1.55 and 0.035 kg, or 35 gm, of gold per metric ton. Where metric system ved the A T weights are useless.

2. Reagents

rge (PbO) is employed in crucible assay to furnish lead for a button; many charges, as a basic flux, oxidizer, and desulphurizer. It should be r silver by fusing 10 A T with silica, borax glass and soda, and enough agent to give a 35-gm lead button. If appreciable bismuth is present, indicated in cupellation by a brown stain at the point where last of the idized. Bismuth causes inaccurate results, for which correction can not , as in case of silver.

m carbonate (Na_2CO_3). Commercial carbonate or soda ash (Na_2CO_3) ently pure for assaying and should be employed. Bicarbonate is un- y, costs more, and is more bulky per unit of Na_2O. Na_2CO_3 acts as a x and in certain cases is a desulphurizer.

Test lead is a solvent for gold and silver. to litharge, which is the principal flux. It m be tested by scorifying four 80-gm portions, until sufficiently reduced for cupellation.

Potassium carbonate (K_2CO_3) performs used with the latter it gives a mixture of low expensive, not essential, and, being hydrosc in moist climates.

Borax ($Na_2B_4O_7 + 10\ H_2O$) is a fusible ac solve many basic oxides. It should always b prepared by fusing commercial borax and pul

Silica (SiO_2) should be considered as an a its melting points, in combination with the than those generally used in assaying. Whe the fusible fluxes is necessary.

Potassium cyanide (KCN) acts as a red is useful in base metal determinations, but should be of good quality. Cyanide conta cyanate is absolutely worthless for some dete

Flour is the most convenient reducing age of lead.

Niter (KNO_3) is used to counteract exces has an oxidizing power of about 4.25 gm lea a determination may be necessary, preferabl occurring in the ore, usually pyrite. Mak pyrite, or enough ore to reduce 15 to 20 gm lea litharge. In one of these charges introduce red heat. Reaction should be completed in and divide difference in weight by 2, giving also acts as a basic flux.

Stock fluxes are advisable when many ass ores, using the proportions given below und desirable to omit niter or reducing agent, ad assays as required.

Reagents for wet analysis and parting unless otherwise stated.

Water. If distilled water can not be ob collected after a portion of the precipitation this, chemically treated water should be used silver assays, where chlorine, generally pre seriously. To prepare water for parting it sh of silver nitrate, heated, and allowed to stand decanted. This water is used for diluting HN portion of water not treated with silver sho and used for second washing.

composition tests. Approximate composition of an ore must be known, to proper charge. When ore is in lump form, this may generally be determined tion. If pulverized, take 5 to 10 gm in a pan or clock glass, add water and our off fine slime and repeat if necessary. Add more water and stratify remain- minerals by panning motion, then determine minerals and their approximate by inspection. Do not attempt to effect a concentration; instead, remove inguishable fine minerals, leaving the coarse particles so segregated that they entified and estimated. Treat about 1 gm of ore with HCl; rapid evolution of tes CARBONATES. Allow complete action, noting percentage dissolved, which ssed as base. Odor of H_2S may give the impression that the action is due to s. Mineral sulphides, however, react slowly with HCl and do not give a rapid of gas. HNO_3 will not answer for this test, as it attacks sulphides vigorously not possible to distinguish between the action of carbonates and sulphides. of chlorine denotes MANGANESE dioxide, and the amount of this mineral present udged by color of sample, remembering that pyrolusite is black. Add strong about 0.25 gm ore, boil, dilute, make ammoniacal, filter or allow to settle. Blue ndicates COPPER, and the percentage may be approximated by the depth of o test for ARSENIC and ANTIMONY, separate the concentrated metallic minerals ning test, and heat with blowpipe, or in porcelain capsule, mixed with a little Characteristic fumes of arsenic and antimony will denote their presence.

4. Crucible Method for Pure Ores

f lead button. Crucible method is recommended for field work, as olicable to all ores, permits use of large, representative samples, and multiplication factor. While the charges vary for different ores the is the same for all. The ore is mixed and fused with such fluxes as will mplete decomposition and solution at a reasonable temperature, thus g the gold and silver. The oxidizing and reducing agents are proper- o produce 20 to 25 gm of lead, which collects the gold and silver in one A lead button of 25 gm is sufficient to collect the values in 1 A T of arger button is not in itself detrimental, but it must be realized that harge is made to yield a button of definite size, all lead reduced in excess amount diminishes the quantity of litharge available as a flux, and reduction may thus seriously affect results. Lead buttons of less than ay or may not collect all the values, and, if adopted, this point should be It is essential that the gold and silver shall be completely liberated l the lead has settled.

n. Manner of fusion is important and varies with different ores. Close n should be given to instructions on this point, which accompany the charges. As a rule, a fusion should be complete in 25 to 35 min. at too low a temperature will affect recovery of both gold and silver; a temperature usually affects only the silver. Do not place crucibles rnace until it is up to working heat.

. A glassy or vitreous slag, which can be drawn into threads when is generally desirable, since a slag of opposite characteristics may indi- omplete decomposition, and may also cause poor collection of lead. lags are produced by having sufficient silica and borax present to form olution with the bases. Character of slag is controlled by these reagents.

Charges for pure ores. Pure ores are rock-forming elements, with small amounts viz, S, As, Sb, Cu, Zn, etc. The problem i that the ore will go completely into solu Na_2CO_3 and PbO, are capable of readily dis bases is rather limited. To decompose basi to combine with the bases in the ore and fl varying amounts of SiO_2 to produce a sla This is indicated in Table 3. In first colum in third column, the charge is for 100% of th for what may be called the neutral ores, whi the base and give a good slag. It is not su compositions indicated in these charges; but base, it is easy to vary the charge accordin than one base is present the charges can be stituents. There is considerable latitude in ore, if enough SiO_2, or even a moderate e combination, and then enough flux to give good results will be obtained. Flour is the u 10 gm lead per gm. Amount required for a the ore often contains reducing or oxidizing a total reducing action, in terms of lead; not or amount of lead desired. (Remarks follow fore making use of the charges.)

s added SiO_2 is considered as ore for the purpose of composing charge, and fusible added accordingly. These charges form silicates and borates with the bases. A T of ore + 15 gm SiO_2 requires same flux as for 1 A T of acid ore. Excess e that required will do no harm, provided sufficient soda and litharge are used. fore apparent that charge (*c*) may be used for 1 A T of acid ore. Borax glass mitted in many charges for siliceous ores, eliminating the more expensive flux. ven when not required, does no harm. In the absence of large amounts of im- da and litharge may be used in these charges to a certain extent interchange- atio of 2 to 3, without objectionable results. Ores frequently contain more As, Sb, Cu, Zn, which should be oxidized. As this can be done only with he charges as given will have the greatest general application. There is no vantage in a charge of the following type, which is in common use: Ore, 0.5 A T; 5 gm; K_2CO_3, 15 gm; borax glass, 15 gm; litharge, 30 gm; flour, 1.75 gm. f litharge in above amount makes it impossible to obtain a lead button too large ation, but this is of doubtful advantage. Any saving in cost of litharge is offset e of potassium carbonate and increase of borax. The amount of reducing agent depends on presence or absence of reducing and oxidizing agents in the ore. e½) up to 13% of the ore, or its equivalent, is permissible with these charges; replaces all the reducing agent, giving a 24-gm button. In charges (*c*), (*g*), (*i*), rger lead buttons are produced because of increase in size of charge. In (*d*), (*e*),), a lead button of 20 to 25 gm is desired, but excess reducing agent is necessary to t oxidizing effect of Fe_2O_3 and MnO_2. In (*f*) and (*g*), manganese as MnO_2 does ilily into solution; high soda interferes with its reduction; borax glass mate- sts dissolution. Charge should be brought rapidly to fusion temperature, the being 1 050° C, or light yellow. Al_2O_3 in combination is a frequent constituent harges *k* and *i*); it slags with difficulty, and interferes with collection of lead. of fluorspar (CaF_2) assists in taking Al_2O_3 into solution. If omitted, soda and ss must be increased 100%.

5. Crucible Method for Impure Ores

include ores containing enough S, As, Sb, Zn, Cu, Ni, Co, and Te, se slag and cupel losses, unless their effect is counteracted. For this ing charge is necessary, and as litharge is the only oxidizing agent which sed in excess, it is employed freely.

pyrite ores containing less than 13% pyrite have been discussed in Those containing over 13% pyrite are treated by either niter or nails

NITER METHOD gives more reliable results for gold and silver, and ad- presence of other impurities. It usually requires a preliminary assay mine reducing power of the ore, and this, together with the large flux nakes it slow and costly. The NAILS CHARGE is capable of direct appli-

Loss in silver. Inquart with silver 2.5 times the weight of gold, flatten bead in dilute (1 to 1) HNO_3, giving two treatments, boiling for 15 min in lask, washing twice. Repeat inquartation and parting. Anneal and ld, plus iridium, if present. Loss in weight is platinum. When only antity of platinum is present, one inquartation and parting with HNO_3 To test for iridium dissolve the gold in cold dilute aqua regia (HNO_3 1, ater 5, parts); residue is iridium. Results obtained as above are fairly and if a check of pure metals, duplicating the assay, is run at same ors are largely eliminated. When palladium is present, the H_2SO_4 s omitted, and the bead treated with HNO_3 as described. In absence um the HNO_3 is nearly neutralized, and palladium is precipitated with glyoxime, heating for an hour and allowing to stand over night. Filter, nd weigh palladium. When platinum is present, repeat inquartation ing if necessary, dilute the solution considerably, precipitate silver with r, evaporate solution nearly to dryness, add HCl, evaporate again, and Add a saturated solution of ammonium chloride and allow to stand over Filter on ashless paper, wash with 75% alcohol, ignite, and weigh. n may be precipitated as described above. Unless errors have compensults will be only approximate.

11. Copper and Lead

llowing methods for copper presuppose that the metal is soluble in Ores which are not decomposed as described require use of hydrofluoric F) or a fusion.

cyanide method" is not suitable for all ores, but where interfering such as Ag, Zn, Ni, Co, and certain other elements to a lesser extent, nt or present in small amounts, the results are remarkably satisfactory. t useful when a large number of determinations are to be made on fairly ore, and a high degree of accuracy is not required. Success with this depends upon a strict uniformity of conditions, as to quantity of chemd, volume and temperature of solution, and rate of adding cyanide. solution, containing 22 gm c p KCN per liter, or one-half that amount rade ores, is standardized against an average sample of the ore to be a check on the solution being run every few days with the ore samples. ontent of standard sample is accurately determined by electrolytic method.

.5 to 1 gm of ore with 10 c c HNO_3, of 1.42 sp gr, in a 6-oz copper flask, or 20 c c 1 to 1) HNO_3 containing 50 gm $KClO_3$ per liter. Boil until all the lower oxides of re expelled, add 25 c c of water and enough ammonia to give an excess of 5 to ually 20 c c. Cool, titrate to a faint blue, filter, drain (washing unnecessary), titration of filtrate. The end point is not particularly sharp, and a definite ust be selected. For large amounts of work, a dozen burettes will be found t. titrating this number of assays at one time, as it is necessary to allow the rate to settle when the end point is approached, in order to observe color of solu- pensing burettes for reagents are a convenience.

method, for accuracy, is not surpassed even by the electrolytic method y carried out, and, as it requires less expensive and elaborate equipment, the preference here. A solution of sodium thiosulphate containing 19 ter, or one-half that strength for low-grade ores, is necessary. STAND- y dissolving 200 mg of copper, or 100 mg for the weak solution, with 1 to 1) HNO_3, in a 6-oz flask. Boil until lower oxides of nitrogen are

If the concen- tains oxidizable material, it is roasted and soluble constituents removed g in strong nitric acid. After drying, mix the concentrate, or a 10-gm of it, with 30 gm of pure potassium or sodium cyanide, and place in a having 5 gm of cyanide in the bottom; cover with another 5 gm. Charge or 20 to 30 min at a good red heat (750° C), cooled, and crucible broken. uncollected tin are recovered by crushing slag and panning.

metric assay. Best wet methods are those of J. J. Beringer (7) and ow (8).

-Low method. Ore must be crushed to at least 100 mesh, and portions of 0.2 are weighed. Add to 5 times its weight of sodium peroxide, and fuse in a nickel Should the ore contain readily oxidized material, melted peroxide is allowed to nd the ore gradually added to the hot mass. The crucible is then given a cir- ion over a burner till a clear melt results. Hold the outer surface of crucible with 50 c c of water in a beaker, till cool; then immerse, and when melt has remove crucible, and wash. Transfer beaker contents to a 600-c c flask. Add Cl, using a portion of this to clean the crucible further, and enough water to otal volume of 400 c c. Strips of nickel having a surface of at least 10 sq in are e flask closed with a stopper fitted with a small funnel or Bunsen valve, and boiling until tin is completely reduced; 25 min is sufficient for 40 mg and 1.5 hr g of tin. Add a crystal of calcite (4 or 5 gm), cool in water. Remove stopper el strips after calcite is completely dissolved, and titrate with iodine solution g 11 gm iodine and 20 gm potassium iodide per liter for a rich product, or one- strength for poor material.

ndardize iodine solution, weigh 0.2 gm pure arsenious acid (As_2O_3), and dissolve a 20% NaOH solution, dilute, acidify with HCl, neutralize with sodium carbon- litmus paper as an indicator; then add 20 c c cold saturated $NaHCO_3$ solution te to a blue color, using starch as indicator. The arsenic standard multiplied by ves value in tin. Iodine solution should be standardized at least once a week.

ering elements are bismuth, titanium, and tungsten. BISMUTH is precipitated during reduction and should be filtered out, the reduction being completed with kel. To eliminate effects of TITANIUM, add the weighed ore, small portions at a 5 gm of $KHSO_4$ melted in a platinum or quartz crucible, and fuse for 5 min. in 60 c c water and 7 c c H_2SO_4. Filter, dry, ignite, and fuse residue with sodium as described. TUNGSTEN, if present, gives a blue precipitate during the reduc- nickel. This is filtered off, and solution again reduced before titration. When and titanium occur together, acid sulphate fusion is described above, and washed residue treated with m carbonate solution, filtered, and washed. This ignited, fused with sodium peroxide, and so on.

15. Coal

mate analysis of coal (9) requires certain standard conditions, as the is arbitrary and results vary with procedure. Crush sample to 0.25-in l if moisture content is likely to change, place a sample in stoppered or a separate moisture determination. The remainder should be air-eating moist sample, if desired, to 70° C, and allowing to cool in the air. portion to 80 or 100 mesh and place in stoppered bottle.

ture. Place 1 gm in crucible and heat to 104° to 107° C for 1 hr. Cool cator, and weigh covered.

ile and combustible matter. Heat 1 gm for 7 min in a 20 to 30-gm cov-tinum crucible, supported by a triangle 6 to 8 cm above top of a Bunsen aving a flame 25 cm high. This test may be made in a muffle at a moderate (950° C), using a clay or porcelain annealing cup, though results will not be l. Moisture must be subtracted from loss in weight thus ascertained.

Burn off the carbon completely from sample used for moisture deter-n, using a low heat at the beginning. This operation may be conducted in um crucible over a Bunsen, or in a clay or porcelain cup in a muffle. If, rying, the sample loses an appreciable amount of water, a determination be made on the original moisture sample, and results corrected.

this is necessary, and percentage of moisture is not over 10%, correction may be l, though not in accordance with the standard method, by weighing out 1 gm e percentage loss of weight in air-drying. Results may then be pointed off in % EXAMPLE: Loss of wt in air-drying, 2.5%. Wt of sample for determination, n. Ash. — Wt of ash, 0.0975 gm; percentage of ash, 9.75%. Moisture. — Loss 0275 gm; moisture in air-dried sample, 2.75%.

1. General Cons

Importance of testing. Before erecting necessary to determine what process will extr profit; this is done by tests on an average desirable to test separately the different class it is practicable to give different treatments economy in the matter of testing is of freq companies have suffered loss by erecting m ores; on the other hand, in some cases large siderable expense to determine points which c rately, and at much less cost and trouble, on

Scale of testing. In general, it is desira a gradually increasing scale. The first test well equipped chemical laboratory, on 1 or of 100 grm or less. The indications obtain subsequent procedure. Results may be co ore per charge, conducted in improvised or together by intelligent mechanics and carpe on ½ to 1 or 2-ton lots, in a small experimen on a large scale may be imitated in most erect such experimental plant may require is complicated. Finally, trial runs may b conditions, in a small plant erected for the voted to experimental work.

2. Preparation of Sample

racy. For precautions necessary to obtain an accurate sample, see Art 31, and Sec 30, Art 3. It need only be pointed out here that results equent tests are misleading unless care has been taken to make sample presentative of material which it is proposed to treat. This applies not the percentage of valuable metal in the ore, but also to the physical er and chemical composition of both valuable and worthless minerals. nature of the ore is liable to vary in different parts of a mine, and arly at different depths, it may often be necessary to test separate representing these various classes of ore. If the mine development already disclosed variation in character of ore, the probability of a ced alteration near ground-water level should not be overlooked.

uction of sample. In reducing a portion of ore for experiment, it is l to avoid treating it in any way which might alter its character; that sample must be so prepared that its behavior in subsequent tests will y indicate the behavior of the ore when similarly treated on a working The process of grinding a sample introduces an appreciable amount of the grinding parts of the machine are of steel. If the presence of this iron would materially affect subsequent tests, it may be removed by ic separator, provided the original ore contains no magnetic material. shing samples, those machines are best which permit quick and thorough g, to avoid danger of enriching a sample of poor ore.

ssible, the sample should be quartered, mixed and reduced to the re- size without drying. Where this is impracticable, the drying should be the lowest possible temperature, and any roasting of sulphides or de- on of hydrated minerals must be carefully avoided. Ores which rapidly o oxidation or other changes, on exposure, should be stored under cover, mple, in closed tins, from which the portions required for small-scale nay be taken immediately before beginning operation. Precautions oxidation are especially necessary with ores on which it is intended to t flotation tests.

3. Screen Tests

e principal objects of screen testing are: (*a*) To judge the character- f a given crusher or system of crushing; for concentration works, in gen- at machine is to be preferred which yields the minimum proportion of zed material, fine slime being particularly objectionable. (*b*) To ascer- lative richness of different sized products of a given ore; the coarsest nts, after a preliminary crushing, may prove to be so nearly barren that n be discarded as waste, while the finest may be so rich as not to require concentration; in same manner, the size below which it will be uneco- l to crush will be indicated. (*c*) To ascertain mechanical efficiency of a rusher; this is based on theory that work performed is in some manner tional to reduction in average diameter of ore particles, after crushing; ties are not agreed as to exact relationship (1).

en openings, mesh, etc. Test is conducted by screening a weighed of ore, sampled in such manner as to insure an accurately representative e of sizes (Sec 28, Art 31), on a set of sieves arranged in order of descend- e of opening. AVERAGE SIZE of a product is then considered to be the etical mean of the diameters of opening in the two screens, through the product has passed and on which it rests. Theoretically, round-hole would be preferred, as yielding more uniformly sized products than -hole or slotted screens, but for practical reasons, since the finer si[illegible]

uch series can be extended in either direction by shifting decimal points.

ution of Mining and Metallurgy series (11) is not based on a fixed screen ratio, approximating the Rittinger series, but is composed of screens commonly used in and readily obtainable. Wires are of same diam as holes; whence, diam of hole ÷ 2 × number of wires per in (e g, holes of a 20-mesh screen are ¼0 in diam); also, openings is 25% of screen area. Screens made to this specification are limited sizes (2.5 mm and less) because of mechanical difficulty of weaving thick wire; the finer end of the series, also, the wire becomes so fine as to lack durability.

er series (12) is based on fixed ratio $\sqrt{2} = 1.26$; whence average volume of a ain in any product will be double that of a grain in next finer product. Also, opening in one screen is twice that of the third following screen. This series eveloped with equal ease in either English or metric units, since it happens that, with 1 in, the fifteenth screen is 0.0394 in, the legal equivalent of 1 mm.

polation of screens. In any series of screens having a fixed geomettio, the following relation exists (13): $S = \sqrt[n+1]{A \div B}$, where S = ratio, mber of screens to be interpolated, A = diam of coarsest hole, B = diam t hole. For example, to interpolate 4 screens between 2 in and 0.25 in, ll be $\sqrt[5]{8} = 1.516$, and the diams will be 0.25, 0.38, 0.58, 0.87, 1.32, 2 in.

autions in test screening. In passing the weighed quantity of crushed ough successive screens, care must be taken to avoid violent rubbing, might enlarge the openings or tear the screen. With fine screens, rable time is required to get the particles to pass, even though crushed ıtly fine; in most cases, long continued shaking, at the same time tape edge of the screen, or lightly rubbing the material over its surface lat cork or rubber stopper will accomplish required separation. No hard as a metal washer or disk, should ever be used for this purpose, as it evitably crush particles which would not otherwise have passed the and will quickly wear holes in wire cloth of fine mesh. U S Bureau of rds, for cement testing, specifies a shaking and gently bumping motion, ıt 200 strokes per min, to be continued until not more than 0.05 gm (200-mesh screen) in 1 min. Investigation has shown (14) that a somewer shaking, about 150 per min, puts a larger ultimate percentage of a ample through the screen; also that use of washers or steel balls in the ields the least reliable results, due to uncertainty of stopping point. nature of material allows, fine screening may be more rapidly and accuccomplished by a jigging motion under water, assisted by a jet of water; ts are settled and dried, after decanting surplus water. If screened dry, ts should be collected in a tightly fitting pan, and screen closely covered, d loss by dusting. A COMBINATION METHOD (15) is to wash and jig the in a pan of water, in the finest screen it is proposed to use for the test, bly using a screen having a metal frame. Fine material is settled, dried, ighed. Material on screen is dried, in the sieve, at a moderate temp oid decrepitation), and then screened in ordinary manner on the coarser This method is more accurate and requires less time for a complete nce stopping point is more distinct on washed sands.

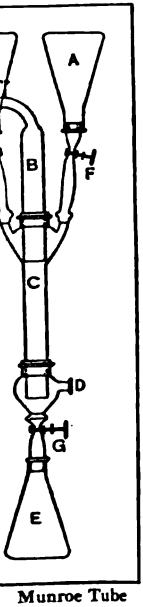
4. Classifier Tests

ts. (*a*) To make sorted (classified) products for further tests on sand concentrators. (*b*) To remove slime from sand, for separate treatment. ascertain relative richness of different sorted products (as in screen . For computations and design of commercial classifiers, see Sec 28, 18. Laboratory tests can be made as follows: Beaker, tube, model inted boxes, or spitzlutten.

r classification (16). Fill a tall beaker with water to a depth of Put in 10 grm of the ore to be tested, stir thoroughly and allow to , say, 40 sec; then pour off the water with its suspended solids quickly ully into a pan. Repeat this operation until the liquid to be decanted A grain which will not settle in 40 sec obviously has a falling ve- less than 2.5 mm per sec. Retaining residue of same ore, fill beaker the mark, stir and allow ore to settle for 20 sec; pour off the liquid econd pan and repeat until all ore settles within the specified time. peration for periods of 10, 5, and 2.5 sec. Allow each decanted portion pour off clear water, and dry and weigh solid matter; also that which n 2.5 sec. The settling velocities of the products made in above man- be respectively 2.5, 5, 10, 20, 40, and above 40 mm per sec; other ve- bviously can be attained by varying depth of water or settling time.



Munroe Tube Classifier

Tube classification (16). A tube classifier, made of glass, is shown in Fig 2. (Designed by H S Munroe, and manufactured by Eimer & Amend, and Emil Greiner, N Y). Joints are made water-tight by short sections of large rubber tubing. To make connection between a rubber tube and neck of a flask, a short section of brass pipe is put inside end of rubber tube and the latter forced firmly into flask. A space of ⅛ in must be left between bottom end of the tube *B* and point of contraction in tube *C*. Nipple *D* is connected by tube to dial cock on water main, and overflow from *B* is conducted by tube to pails or pans. Knowing inside sectional area of column, compute volumes of water necessary to give rising currents of any desired velocities ($q = av$). If computations are in metric system, a liter graduated jar can be used for measuring volumes.

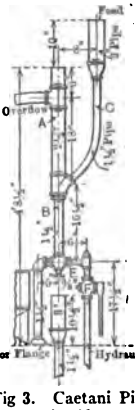


Fig 3. Caetani Pipe Classifier

A weighed sample of ore is divided about equally between the two flasks *A*. Enough water is added to moisten ore thoroughly, with shaking; bottles are then filled with water, and put into position for feeding, the cocks *F* being closed. The rubber tubes must be full of water both above and below *F*, because an air bubble prevents iscbarge of ore. Having adjusted flow of water up the column to desired velocity, are slightly opened to allow ore to drop slowly. Light material will be carried over, e heavier will fall through rising current and into flask *E* at bottom. When all ore upper flasks, a few minutes are allowed for sorting column to clear partially, cur-

Two forms used in the Columbia School of Mines are shown in Fig 4 and 5. In ng rising velocities in inclined channels, measurements of sectional area should horizontally, not normal to walls of channel, since it is the vertical falling velocity s that is under consideration. A sorting tube underneath the apex of cone or box is an essential feature if well classified products are desired. A convenient by which to draw off classified products continuously, while maintaining a rising in sorting tube, is to use a 2-necked Wolff bottle, joining one neck to bottom of tube (being careful to avoid constriction) and connecting other to water cock. elocity in sorting tube should be adjusted to about one-fourth that in free-set- mber above it, to compensate for hindered settling conditions (Sec 28, Art 17).

5. Concentration Tests

d-picking often affords valuable information, even when not considered icable method of treating a given ore under existing conditions. It may ied to ore as fine as pea sizes; for example, to determine proportions of d included mineral in jig middlings. For satisfactory hand-picking, ore be sized between rather close limits, and should be clean; washing also out distinctive color or luster of some minerals (27).

icability of hand-picking on a commercial scale may be tested by attempting the following products, or so many of them as practicable (16): (*a*) RICH MIN- t for market or for metallurgical treatment. These will include not only such as galena, blende, chalcopyrite, etc, nearly or quite pure, but also rich material ossibly can be treated better by some metallurgical process than by mechanical for example copper carbonates, silver chloride, finely disseminated silver ore,) Rich ore, with COARSE DISSEMINATED MINERAL, for coarse crushing and jigging. ntains minerals not easily separated by gravity methods, several classes may be this rich ore. For example, pyritiferous lead ore should be separated from lead aining blende, and ore with a barite gangue from ore with a quartzose or calca- angue. (*c*) POOR ORE, with coarse disseminated mineral, suitable for coarse and jigging, but less rich than the above. (*d*) FINE DISSEMINATED ORE, usu- r, so-called "stamp-rock," in which the useful mineral occurs in such small par- at exceedingly fine crushing will be necessary to liberate it. There are ores in he valuable mineral is so finely disseminated that mechanical treatment is im- ble. (*e*) BARREN WASTE, or material that does not seem to be mineralized. classes may sometimes be made of this, according to gangue minerals or rocks in or when a difference of color, texture, or other characteristic indicates a possible e in richness. Assays of these different classes of barren or seemingly barren will show which may be thrown away, and which should be included with the mechanical treatment. Finally, inspection of the different products may show ne classes are present in small quantity only, and that perhaps several sorts may ined without disadvantage.

d jigging, for testing ore ranging in size from 10 to 2 mm, requires only of water and a few small screens of differing mesh. Before jigging, the ould be sized fairly closely (16).

bout 2 in depth of sized ore into a sieve having mesh fine enough to retain it, and several minutes under surface of water, with a long, slow stroke for coarser sizes of a shorter and quicker stroke for finer sizes. A quick down stroke combined with r up stroke will be found most effective. Care should be taken to keep sieve level avoid any horizontal or overturning movement of the mass of ore. When tailings to be clean, upper layer may be scraped off and replaced with an equal amount and jigging resumed. Middlings and concentrates may be allowed to accumu- sieve, unless these layers become inconveniently thick. Main object of this pre- y jigging is to produce tailings as poor as possible. When whole sample has us treated, accumulated concentrate is first cleaned by careful jigging, aided by cking if necessary. Skimmings from this cleaning of concentrate are added to ddlings first obtained. All middlings are now rejigged and reduced to smallest e bulk, by separating as much concentrate and tailing as possible. It is sometimes e to make two or more grades of middlings, the richness of which may be tested

separately to determine the effect of combining
or with this. Assays of products, and close
different sizes as are tested, will indicate maxi
be used.

Machine jigging. Experimental jigs for tes
are made by the Denver, Colo. and

heavy mineral, the latter is drawn off through stop-cock. Brögger's apparatus, ng of two bulbs in tandem, with stop-cock between, is better than simple funnel.

ions available for this purpose are: SONSTADT; H_2O sol of KI and $HgCl_2$ (sp gr diluted to any desired sp gr with H_2O. THOULET; 210 gm KI, 260 gm HgI_2, d in 25 cc H_2O (sp gr 3.196); can be diluted with H_2O. KLEIN; saturated H_2O sol ium borotungstate (sp gr 3.281); must be prepared by a chemist, and is expensive; diluted with H_2O. ROHRBACH; 100 gm BaCl, 130 gm HgI_2, dissolved in 20 cc temp of 150° to 200° C on an oil bath (sp gr 3.58); can not be diluted with H_2O, nstable. BRAUN; commercial methylene iodide (sp gr 3.31 at 25° C); can be with benzol. RETGERS; double nitrate of silver and thallium fuses at 75° C to of 4.5 sp gr, which can be diluted with hot water. BIEDERMAN; mercurous uses at 76° C to a liquid of 5.3 sp gr, which can be diluted with hot water. MUTH- cetylene tetrabromide (sp gr 2.95). BROMOFORM (sp gr 2.82) diluted with benzol .88) is cheap and easily manipulated. Saturated sol of ZINC SULPHATE (sp gr 1.5) t some coals. Solutions containing Ag or Hg must be handled with great care; ntaining I or Br are liable to discoloration on exposure to sunlight; those con- nitrates may attack certain minerals, rendering subsequent analysis misleading.

ion necessary to afford a solution of desired sp gr can be computed from: $v_1 = d) \div (d - d_1)$, where v = vol of heavy sol; D = its sp gr; d = desired sp gr; gr of diluting liquid; v_1 = vol of diluting liquid to be added.

ific gravities of both liquids and minerals are most conveniently determined with c-gravity bottle (a thin glass bulb of 25 to 50 cc capacity, having a close fitting pper pierced by a capillary tube so that bulb will always hold a constant volume d, at a given temp). For LIQUIDS, weigh flask empty, clean, and dry (b); then ith distilled water (w); finally, filled with the liquid (W). Sp gr of latter =) $\div$ ($w - b$). For MINERALS, first weigh flask full of water (B), individual weights and water being immaterial; then add weighed amount (M) of dry mineral in agments, allowing displaced water to overflow; and detaching bubbles by stirring, ssary; finally replace capillary stopper and weigh flask and all its contents (A). mineral = $M \div (B + M - A)$.

les for testing sands and slimes can readily be improvised; for example, section of steel channel, or a shallow trough made of planed board or ith linoleum, and resting on adjustable supports, will closely simulate a (27).

re elaborate form (designed by H S Munroe and made by Eimer & Amend, ig 6) consists of a strong metal frame about 5 ft long in which flat plates of pine,

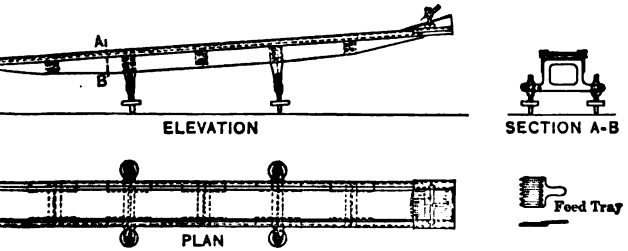

Fig 6. Munroe Laboratory Slime Table

slate, glass or other material may be secured (18). These plates are held by . and the joint between frame and plate is made tight by inserting a strand of wicking. Inclination of table is adjusted by leveling screws, and amount of by dial cock. These adjustments are controlled by testing a small sample of the l to be treated, and giving to the table such inclination and amount of water as fect the desired separation. Data for these adjustments are given in *Trans* E, Vol 27: p 76. It will be found more rapid to adopt somewhat more water and

less inclination of table than recommended in t
washing, reserving the steeper inclinations and re
retreatment of middlings.

A portion of wet ore, preferably classified, is
head of table, care being taken not to feed too fa
rupted and material on the table is washed 2 or 3
off. Tailings pan is then removed, and middli
washed off with a jet of water, into separate pans.

ability. Thus far, flotation processes have been most successful on ores of zinc and copper; there is no obvious reason, however, why should not be applied to ores containing other sulphides, arsenides, etc, metals (19). Oxide, sulphate, and carbonate minerals have not yet ted successfully, and ores containing over 5% $CaCO_3$ are considered too of acid; in some cases associated sulphides may be floated without acid. on of sulphides from one another by flotation is not yet wholly satisfac- re should be crushed to 60-mesh or finer, but sizing is not necessary; in h processes are found to be improved by presence of slimed sulphides. gests applicability of flotation to finely disseminated ores or tailings. in smelting concentrates in finely divided form is one obstacle to more use of flotation. THOROUGH PRELIMINARY TESTING is particularly advis- re installing flotation process, because the relatively feeble forces of and surface tension, not fully understood, may be adversely influenced unconsidered condition; thus, a porphyry copper ore, suitable for flota- n freshly broken, might prove refractory, due to slight oxidation, after for a time in a stope or on a dump (20). Methods are of 2 general

on, speed and duration. Adopting most efficient conditions ascertained as y result of diminished speed of agitation, with a view, if possible, to reducing al energy required in a commercial installation. In general, the more ener- agitation, the more complete is the extraction. In laboratory apparatus having f 4 in diam, a speed of 1 500 rev per min (equivalent to peripheral speed of er min) is recommended. DURATION tests may cover periods of, say, 1 to 8 min, covery and richness of concentrate. In general, longer agitation gives higher but at expense of impure concentrate; shorter agitation requires more oil to sh a desired recovery.

ss of crushing. Make screen analysis of tailings from any preceding test s shown fairly satisfactory recovery, and assay each size. Losses will usually be coarser sizes, and if they are considered excessive, desirability of finer crushing ed. Erroneous results would be given by first sizing the ore and then attempt- at the sizes separately, since commercial methods are always applied to unsized presence of slimed ore seems to be advantageous to froth processes.

7. Amalgamation Tests

amalgamation. A sample of the ore, previously crushed to, say, o-mesh, is ground for a definite length of time in a Wedgwood or an rtar, with addition of mercury and such ingredients as would be used ice; for example, caustic soda, salt, copper sulphate, or sulphuric acid. owing mixture is commonly used: ore, 300 gm; water, 100 cc; caustic gm; mercury, 50 gm. Grind for 1 hr, pan off the mercury, dry and e residue, and calculate extraction.

mall test of this nature, results calculated from DIRECT DETERMINATION of the silver taken up by the mercury are seldom reliable, owing both to the difficulty ing mercury quite free from these metals, and to the likelihood of loss while ff the excess mercury by heat, or dissolving it in acid. If it is desired to make ect determination, either of the following methods is convenient: (*a*) ACID NT. The mercury used in the test (say about 50 gm) is collected in a single by careful panning, and washed free from every particle of adhering matter. heated gently in a casserole or large porcelain crucible with about 20 cc of dilute id (1 vol strong HNO_3 to 2 vol water) so long as reaction continues. From time, the liquid is poured off and replaced by fresh acid, so as to avoid too great tration of dissolved salts, causing crystallization of mercuric nitrate. Finally, ining bead of gold is washed several times with hot water, dried very cautiously, ited and weighed. It is best to wrap it in a small piece of lead foil, and cupel eighing, as it may retain impurities insoluble in nitric acid. (*b*) HEAT TREAT- Put gold-bearing globule of mercury into scorifier. Invert a smaller scorifier, small hole bored through its bottom, over first scorifier, and lute with fire clay. ry carefully in mouth of muffle until no more mercury will condense on cold d over vent in scorifier. Remove top scorifier, add a little test lead and borax orify and cupel lead button. Part and weigh as usual (Sec 30, Art 6–8). Heat has advantage of not requiring such careful coalescing and cleaning of mercury before treatment, since any adhering silica, magnetite, etc, can be slagged off corification.

ening of mercury, through the action of certain minerals or the pres- grease, talc, base metals, etc, in the ore, makes it difficult and tedious to e from the residue, by panning. In such cases the addition of caustic odium amalgam, or sal ammoniac may assist in causing the mercury to n a single globule. SODIUM AMALGAM may be made by adding metallic , in very small pieces, to a quantity of mercury contained in a large . Each fragment of sodium, as it is pressed beneath the surface of the y, produces a slight explosion as it amalgamates. About 2% of sodium e conveniently added in this way.

tained at given strength, will often be muc
test in which most of the cyanide was destro

Example showing method of maintaining KCN solution originally taken; total cyanide agitation with ore, 50 cc taken out, after standi 0.19% KCN; remaining solution, 150 cc at 0.19 added to make up strength = 0.50 − 0.285 = 0 solution containing 1.05% KCN; then 20.5 cc Measure out 20.5 cc of the strong solution, dilute the test. This gives us 200 cc, containing altog 0.25%.

Time of treatment. Assuming previou 0.25% KCN, run tests with (say) 100 gm o tion, 1.5 gm lime, stopping treatment succe 96 hr. Test solutions and assay residues.

It may sometimes be desirable to vary two or m if a strength of 0.25% KCN gives the best result sarily follow that this strength of solution will be agitation. Where facilities permit, a large numb may be made simultaneously, thus shortening tim

Percolation tests. Whenever the results without extremely fine grinding, it become would not be advantageous for at least a po test may be made.

Crush (say) 20 to 100 lb of ore to pass 40-mesh classification, or by repeated stirring with wate sandy portion as dry as possible, mix thoroughly and on an average sample determine moisture an in proportion determined by previous acidity tes tank. This may be an inverted glass bottle with b of a small cask. Filter-bed is required, which m framework of wooden slats, covered with thin can canvas cover. The edge of the filter-frame must or similar material. An outlet for the leaching frame, the flow of liquid being regulated by rubb Only a little space must be left between filter-fra tions are added at intervals, say once or twice a da of ore each time. A good plan is to begin with a ore; then follow with strong solution, draining off a is saturated with it; then add enough strong solut stand, with outlet closed, for at least 24 hr. Afte sively weaker solution may be given, ending with the original moisture of the sand treated. Each s pletely as possible before applying the next, to se mum of liquid. The charge may be sampled at i care to get a correct average from top to bottom, an of the charge. If all the solutions drawn off are alkali, a very fair estimate may be made of the pr working scale. Finally, the entire charge should be and assayed. A portion may also be tested afte filter.

Aeration tests are generally made in sma struction of the Pachuca or other form of a air supply requires careful attention; if ins if too abundant, consumption of chemicals m to compare results from aeration tests with th aeration, but under otherwise similar conditio

ests. A great variety of conditions may occur in different ores, which may an elaborate research into such questions as the necessity or disadvantage ary water-wash, acid-wash, or alkali-wash, oxidizing agents, roasting, concen- algamation, or other process, and the use of additional reagents during cya- ent, such as bromocyanide, lead salts, etc. These tests cannot be detailed he same principles apply as in those above described. Results should be con- larger-scale tests. In general, WATER-WASHING is advisable for partially oxi- containing iron or copper sulphides, and ACID WASHING is also frequently bene- r the same conditions, particularly where basic sulphates insoluble in water . ALKALI WASHES may be advisable with arsenical and antimonial ores; for he preliminary desulphurizing process with caustic alkali and aluminum may useful (28). OXIDIZING AGENTS improve extraction from certain ores contain- idizable sulphides and certain kinds of organic matter; preliminary treatment anganate, with or without dilute sulphuric acid, is sometimes advantageous conditions are present. ROASTING is beneficial and sometimes essential with ning heavy sulphides, arsenides, sulpharsecides, tellurides, etc, but the cost ation, in comparison with the possible increased saving of valuable metals, ays be considered. CONCENTRATION is often advantageous when values are with sulphides or other heavy minerals, provided that the latter do not con- large a percentage of the ore. AMALGAMATION should always be tried in coarse gold and perhaps, also, of native silver. BROMOCYANIDE has been ly successful only with telluride and with mispickel ores.

tation tests may be made by causing a sufficient volume of solution hrough a model zinc-box or, less satisfactorily, through a vertical osely packed with zinc shavings, at a definite rate for a measured f time, varying these conditions in successive tests. Samples of the ntering and leaving the box are analyzed for precious metals, cya- alkali. Tests on ZINC or ALUMINUM DUST precipitation may be made ng (say) 0.5 gm of the former or 0.1 gm of the latter with 100 cc of or silver-bearing solution in a stoppered bottle for 5 min, filtering a vacuum filter, and assaying filtrate. Recovery of silver may be sted by dissolving the precipitate collected on the filter in dilute , and titrating the silver by Volhard's method. Proportions given suitable in many cases, but should be varied to find the most effec- ions.

n tests. At the end of every test, and sometimes at other stages of solutions are tested for free cyanide, alkalinity or acidity, and occa- determination of gold or silver contents is useful as a check on com- f extraction based on original and final assays.

nide. Titrate with standard silver nitrate until a cloudiness or opalescence manent. Many operators add a few drops of strong potassium iodide as an this titration. Standard silver solution commonly used contains 13.04 gm litre, so that 1 cc = 0.01 gm KCN. Some practice is required for determin- finishing point in impure solutions.

y or acidity is determined in the same or another portion of solution, after $AgNO_3$ until distinctly turbid. Add phenolphthalein and titrate with stand- alkali, as the case may be, until the pink color disappears or appears. Alka- culated in terms of NaOH, KOH or CaO; acidity is usually calculated as

y be rapidly estimated by J. Moir's colorimetric method (24). Cyanide is y boiling with sodium peroxide; lead acetate and aluminum dust are then ssively, the precipitate is filtered off, redissolved in aqua regia, and strong loride is added drop by drop until the yellow color disappears. On standing urple color develops and reaches its maximum. The tint is then compared btained from known amounts of gold, in a standard gold chloride solution, the same amount of stannous chloride.

etails of this and other solution tests, see Bibliog (25).

9. Other Wet Extra

Chlorination process is usually applied in which gold is the valuable constituent crushed, is roasted at a moderate temp 100 gm, this may be done in ordinary clay Larger quantities may be spread on floor tests, a small reverberatory furnace lined w

Roasting. Charge is turned over from time t by a piece of stout wire, having one end flatt finish of the roast, when most of the sulphur, ar been expelled, the temp is raised to a moderate withdrawn and allowed to cool. Roasting may not be hurried.

Chlorinating. Roasted charge is now slig over a specially prepared filter bed. For small disk horizontally inside a large funnel, and co glass beads, or similar material on which chlori with flat perforated diaphragm, used for vacuu purpose. A larger test should be made in a s layers of pebbles decreasing in size from below u should be provided. Chlorine gas is then intro diffuse upwards until it begins to issue from ben over the top. The chlorine may be generated parts sulphuric acid and 9 parts manganese di and potassium permanganate; (*c*) chloride of charge is indicated by smell of the issuing gas, o of an ammonia bottle is held near edge of cove from chlorine generator, and cover luted on wit inlet also being closed. Action of the enclose turbed for several hours, in some cases overnigh

Leaching. Charge is then leached with wat through the porous bed, are collected. Washin assayed for gold, or entire gold contents may hydrogen sulphide, collected and assayed. In l for settlement of precipitate (say 48 hr). Wa assayed, when extraction may be checked by di

Acid treatment. Important developm of copper render it necessary to have some to acid treatment. As in cyanide treatm in bottles, varying such conditions as finen tion of pulp, and percentage of sulphuric a be assayed not only for copper but for oth are likely to be extracted; the amount o determined. Nature and amount of the di the causes of acid consumption.

Acid-resisting material becomes importan should be painted internally with some acid-res be avoided so far as possible where exposed to a erally suitable for this purpose; it appears to be hydrocarbon in carbon bisulphide. Various for been introduced as filtering media, and may adv filter for percolation tests. Certain ACID-RES and others, may be useful for pipe-fittings, pu use of metal is unavoidable.

STANFORD LIBRARIES

t quantity of iron filings, using various proportions until best conditions are d. For larger quantities, solution may be passed through a launder contain- fragments of hoop iron, etc. ELECTROLYTIC tests require special apparatus, uments for measuring quantity and potential of current. If strong currents ary, the designing of cells composed of, or lined with, some insulating material mportant. Tests on composition of electrolyte, and of products deposited at e and cathode must be made at intervals. Electrolytic processes suggested ent of copper ores generally require an iron anode; ferric sulphate is produced ctrolysis, and its solution is used as solvent for further quantities of copper.

treatment is used chiefly for extraction of antimony and arsenic, lly as a preliminary step, before applying some other solvent for re- precious metals. Methods of investigation are sufficiently indicated sts previously described. Sulphides and polysulphides of sodium or are occasionally used as solvents for ores of this class. In designing s for large-scale tests, the action of caustic alkalies on the material construction must be considered. Silica ware suitable for acid treat- y be found unsuitable in this connection. Iron tanks and fittings rally be used with alkali solutions of ordinary strength.

ulphite treatment is used for ores in which the value is mainly uch ores are generally given a chloridizing roast, and this operation refore be imitated when testing the suitability of an ore for this treat- ometimes it is desirable to give a preliminary oxidizing roast, as de- nder chlorination; in other cases, the required amount of salt may be th the raw ore.

izing roast. Tests may be made in roasting dishes in a muffle, but the kl be carefully regulated and not allowed to rise above dull redness. Since this process depends on a reaction between chlorine, generated from the salt, minerals in the ore, excessive stirring after addition of salt should be avoided; st results are obtained by covering the charge at a certain stage, and allowing o proceed undisturbed. A partial oxidizing roast before adding salt has the nverting iron sulphides into sulphates, which latter react with the salt, forming lphate and liberating chlorine. In some cases it may be advantageous to add lphate, sulphur, or other chemicals, along with the salt. Many experiments ring conditions may sometimes be necessary before best method of roasting is d; thus, proportion of salt, length of time in furnace, stage at which salt is n of final roast, and advisability of preliminary oxidizing, are among the bles. Losses of gold and silver in chloridizing roast are increased by presence elements, such as arsenic, antimony, tellurium, or selenium. When these are sses may be reduced by eliminating such volatile substances as far as possible inary oxidizing roast, before adding salt. Having obtained a satisfactory necessary to determine what loss of weight and of precious metals has occurred, excessive, such losses may counterbalance the advantage gained by a high in subsequent leaching. All charges should, therefore, be carefully weighed, nd assayed, before and after roasting.

lphite leaching is done in much the same manner as cyanide treatment. ases, hot solutions may be advantageous. Strength may be varied from (say) % or more. Sometimes a preliminary water-wash may be given, and occa- dium carbonate is added to precipitate lead in the extract. After the ordinary ite treatment, a wash is sometimes given with an "extra" solution, containing hyposulphite of copper and sodium, which dissolves an additional amount of ompletion of extraction in leaching tests is shown by ceasing of the effluent o react with sodium sulphide, though a reaction with sodium sulphide may in- d, copper, or other metal besides silver. Both solutions and residues should l for silver.

ction. This section deals briefly with some of the metallurgical problems relat- disposal of ores after they have been mined, and which are of interest to mining To cover the subject thoroughly would require citation and discussion of schedules, which would be out of place here.

n ore is of constant character and value, as is common, for example, in case of inc, fixed and definite terms can be formulated for sale or purchase. But, for complex ores, special terms and quotations are necessary, which are sometimes comprehend. Most non-ferrous reduction works receive heterogeneous ores, more or less complicated schedules and terms of settlement. Moreover, as local in different ore-producing centers often vary widely, schedules applicable to t may require radical modification in another. Rates are seldom intentionally plex, but in certain cases it must be admitted that they could be simplified, for mprehension by small shippers. NOTE. — The prices and rates given below he period antedating the Great War; the present conditions are abnormal.

1. Smelting Ores; Fluxes

pal questions relating to sale and purchase are: (*a*) freight rates; od of sampling; (*c*) composition of the ore; (*d*) fluxing requirements e a satisfactory slag, and available fluxes at the smelter, either in shape material or other classes of ore; (*e*) value of recoverable metals; (*f*) of impurities contained in the ore; (*g*) cost of treatment and refining; l losses occurring in treatment; (*i*) interest on value of metals tied up reatment and commission for selling metals; (*j*) terms of payment; ment charge; (*l*) interest and amortization on plant.

shipper of silicious ore may be returned as b

Examples. If limestone containing 52% CaO a
at smelter, and the cost of smelting a prepared or
direct smelting cost will be $3.36, which, divided
(52 units, less 4 units of CaO required to flux the
larly, if an ore containing 59% Fe and 5% SiO_2, v
delivered, $2.50 per ton more than the value of th
cost is $2.50, the total cost of $5, divided by 50
flux SiO_2) gives a cost of 10¢ per unit.

If it be desired to make a slag containing 36%
CaO, the cost for SiO_2 is determined thus: 29 un
7¢ = $1.33, total $4.23, which covers cost of fluxi
per unit of SiO_2 equals 11.75¢, say 12¢. Under
7¢ a unit, Fe at 10¢, and SiO_2 charged for at 12¢

Fe is usually obtained from special ores contain
to such a limited extent in most ores that it must b
quarried as near the smelter as possible.

2. Value of Products; Influence of Impurities

e of recoverable metals is determined by analysis and assay of the (Art 1). The principal metals in smelting ores are Pb, Cu, Au and Ag.

d Cu are reported in percentages. The value of Cu is determined by the standard n per lb; of Pb by the quotation per lb or unit. A UNIT is 1% of a ton, or 20 lb. Ag are reported in Troy oz per ton of 2 000 lb; value of Au is fixed at $20.67 per z. by quotation. In determining the value of Cu, Pb and Ag, it is specified that ation used shall be that of a certain date. The buyer usually pays for the ore making allowance for the time he has to carry the values in the ore. Sometimes ified that the quotation used shall be that of a certain number of days after settle- assay (30, 60, or even 90 days); during which period the metals may be recovered melter and sold at approximately the price that is paid for them.

ence of impurities has an important bearing on the value of an ore on the price paid for it. If the impurities are small in amount, they re- attention. But, if there is possibility that the ore contains impurities tent that will interfere with reduction and recovery of metals, penalties osed.

pal Impurities. SULPHUR in copper ores is not detrimental and is seldom pe- But sulphur in lead ores, if above a certain limit, makes roasting necessary. As eases treatment cost, an ore containing more than say 4% S is penalized on the 15 to 25¢ per unit in excess of that amount, up to a maximum of $2 per ton. pecially as blende, creates irregularities in smelting; part goes into the matte part into the slag, making it pasty, and part is volatilized, causing trouble in the and increasing silver losses by volatilization. The usual limit is 10% Zn; at elters, all in excess of 5% is penalized. The charge for excess Zn is 25 to 50¢ per ARSENIC is usually penalized in lead, and frequently in copper ore. With lead, it EISS (Art 3), a troublesome by-product difficult to retreat; with copper, some of reduced in the bullion, increasing refining cost. The penalty varies greatly, and figures can be given; it is sometimes 20 to 25¢ per unit in excess of 3 to 5%. RY is also troublesome, but is seldom penalized, as it is more easily treated than refining a lead bullion from a Pb-Ag ore, part of the Sb is recovered as antimonial

3. Treatment: Methods and Costs

lting operations comprise: (*a*) roasting the ore; (*b*) furnace treatment; ning the metal or metallic compound from the furnace, and treatment of ucts. The principal by-products are MATTE, an artificial sulphide of r metals, and SPEISS, an artificial arsenide of Fe, or antimonide of Cu. re retreated to recover metals. Under (*c*) are included: refining lead converting copper matte, and refining copper bullion. Fig 1, 2 illustrate plicated processes for producing Pb, Cu, Ag and Au from their ores.

of each treatment step must be considered in fixing the terms for purchasing an these costs vary with local conditions at the smelting plants.

eral basic costs for large plants are: for lead smelting operations, cost of charge, $2.50 to $3.50; for copper smelting, cost per ton charge, $1.50 o; for refining lead, $4 to $6 per ton of bullion; for converting copper about $8 per ton blister copper produced; for refining copper, $11 to $13 bullion. Cost for smelting lead- or copper-bearing material may exceed smelting per ton of charge. Costs at comparatively small plants are igher than for large. Interest and amortization should always be con- in costs.

l losses in smelting and refining. In LEAD ORE, loss of Pb varies from %, depending upon percentage of Pb, and upon whether refractory or The lower limit is for a charge carrying about 40% Pb; the higher, for a carrying about 10–12% Pb. Copper loss in lead smelting sometim[redacted]

reaches 30%, as the amount of Cu permis
limited. In smelting COPPER ORE, the loss
but the recovery is always much higher t
small, from 2 to 5%, unless conditions ar
small, and is not usually considered.

Interest and commission are relatively small
settlement of assay, interest is allowed on the valu
pending upon how soon they can be recovered. But, if the metals are not paid for until sufficient time is allowed for their recovery, no interest charge should be made. Commission for selling is usually allowed for in the net price received for refined metals.

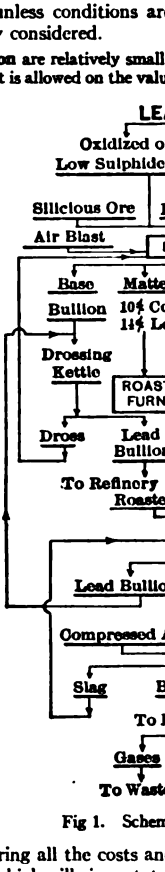

Fig 1. Schem

4. Terms of Payment for Metals

Factors. In purchasing any class of ore all the points stated in the beginning of Art 1 must be considered. From (*e*) is found the value of recoverable metals, and from (*j*) the amount paid for them, the difference being the MARGIN ON METALS. From (*c*) and (*d*) result the premium or penalty for basic or silicious ores, and from (*f*) the penalty for impurities. Cost of treatment (*g*) and losses of metals (*h*) are determined from records and experience in the smelting plant. Treatment charge (*k*) is then fixed by considering all the costs an to this margin a charge which will give a tota desired. Thus the greater the margin on need be, to secure a given profit. (The tre trary figure, acting as a balance wheel.)

The gross value of an ore to the smelter is th constituent arrived at by taking market quotatio freight and refining. The term GROSS MARGIN value of metals present and the amount paid fo losses of metals, and profit (*i*).

Gold is usually paid for on basis of 100% of th but no payment is made when the ore contains

or rich ore; the lower, for poor. As there is little or no loss of Au in ordinary operations, the difference between the value of the Au and the amount paid for an covers the carrying interest and losses, and therefore adds to the margin on the ore.

is usually paid for on basis of 95% of the ore content, at N Y quotation per Troy silver at the time agreed upon. No payment is made if the ore contains less o 1 oz Ag. More Ag is recovered in smelting than is usually paid for, the differng to the margin on metals, as in case of gold (11).

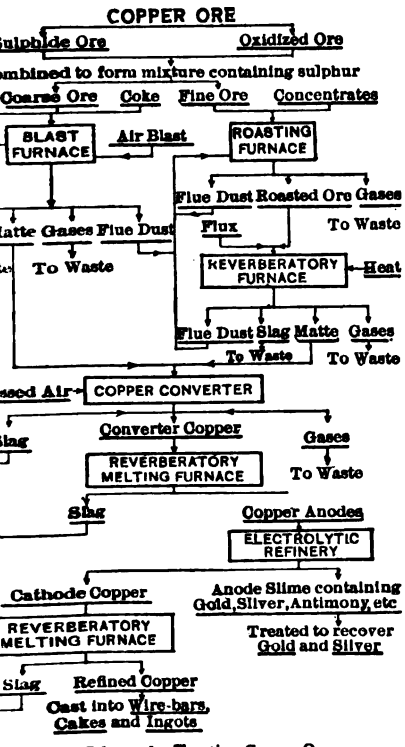

Fig 2. Scheme for Treating Copper Ores

Lead. Many different terms are used in making quotations. The most common is to pay for 90% of the Pb content of the ore, at a certain price per unit. The 10% allowance is supposed to cover smelting loss, and in making it the variation in Pb content does not affect subsequent terms or conditions. The payment is on basis of the quotations, less the cost for freight to refinery, refining lead bullion, and the selling charges. If the Pb content is less than about 5%, it is not paid for. Freight and refining usually cost about $20 per ton, depending upon conditions; hence, if price of Pb is 4¢ in N Y, the price paid in Colo (to allow for freight and refining) would be 4¢ less 1¢, or 3¢ per lb (11). If an ore contains 20% lead, or 400 lb per ton, 90% of this (360 lb) would be paid for on the above basis, at 3¢ per lb (= 60¢ per unit), or a total payment of 18 units × 60¢ = $10.80 per ton of ore. (For local schedules, see Bib 1, 7, 11, 14, 15.) Mode of assay (Sec 30). Wet assay is exact and is preferable for the seller. Dry assay (by fire) is usually lower (1% to 2% lower) assay, and, if it be used, the purchaser pays correspondingly less for the metals. y has more effect on the returns from a low-grade than a high-grade ore. Thus, ontaining 40% Pb might show by dry assay only 38% (difference, 5%); or a might show only 18% (difference, 10%). In the latter case, 90% of 18% Pb paid for (324 lb instead of 360), which, at 60¢ per unit, gives $9.72 instead of Payment is made on basis of 90% of the corrected assay, which equals the wet is a specified allowance of usually 1.5 units.

r was formerly paid for on basis of the dry or Cornish assay, estimated at about less than the amount of Cu in the ore. This difference was supposed to cover u in old methods of treatment. This assay is now seldom used, Cu being paid asis of the wet (electrolytic) assay, less a certain percentage (usually 0.5 to 1

included, and may considerably affect the appare

tatement shows that the value of the metals at the smeltery is $43.35, while the paid for them is $37.87, a difference of $5.48; which, deducting the Pb, Ag and of $1.84, leaves $3.64 in favor of the purchaser. Though this is not an actual metals, it enables the purchaser to fix a lower treatment charge; in this case, $2 hich is much less than the cost of roasting and smelting. If the margin on metals uced, the treatment charge would have to be correspondingly increased, to ob- profit shown.

asons already given, it is advantageous to allow for losses in quoting on metals, o doing the seller suffers no hardship. The premium paid for Fe and CaO, and levied for SiO_2, are considered in the outcome. The ore, because of its Fe and tent, has an added value equal to the premium paid, and the excess cost, due to which must be fluxed, is considered in treating, this excess being the amount of lty for SiO_2 in the purchase statement. Since the deduction for Zn is considered oss margin, it might seem that it should also appear in the outcome as a cost. is difficult to arrange. Excess Zn increases losses and treatment cost, but the of increase for different classes of ore is not readily determined. For average ore, s and costs are ascertained from the metallurgical results, which furnish the only a (6, 8, 9).

tain localities, as in parts of Colo, ores of uniform character, having their chief Ag and Au, are sold on a FLAT SCHEDULE, no attention being given to ore composi- his schedule is based on a sliding scale, depending on value of ore (1). Treat- arge on low-grade ore is such as to stimulate its production; higher-grade ore d a higher charge. The charge for a Pb or Cu ore frequently decreases as the creases, because: (*a*) an ore of high metal content makes less slag; (*b*) the Pb, a valuable collector for Au and Ag.

ent forms are used for making ore purchase calculations. The table on following ranged by C. S. Witherell) is comprehensive, and includes all the steps required ning ore or bullion value, margin on metals, premiums and penalties, detailed for nt costs and profit.

ores. The purchasing terms are entirely different from those for Ag . Zn ore is mostly sold in open market at a base rate per ton of sulphide ncentrate) containing 60% Zn, a premium of about $1 being paid per unit , and $1 penalty charged per unit under 60. A charge may also be made and Fe. The flat price per ton varies with conditions.

rice usually obtainable for Zn ore or concentrate delivered at smeltery is shown by ula: $(T - 8) \times 20 \times$ price of Zn per lb $- \$16 \pm$ = value at the smelter; in = units of Zn and $16 the treatment charge (W. R. Ingalls). Thus, a concen- taining 59% Zn would be worth, at 5¢ per lb at St Louis, $(59 - 8) \times 20 \times 5¢ -$ 55. In Europe, smelteries generally purchase Zn by the formula,

$$V = 0.95\, P \times \frac{T - 8}{100} - R,$$

V = value, £ per long ton; P = price of ordinary brands of Zn in London (per); T = units of Zn in the ore; and R = treatment charge per long ton (2). The n of 8 is to cover treatment losses, which are quite constant, regardless of the Zn (16).

ore is purchased at flat rate, depending upon the percentage of Fe, with penalty below a certain grade, and a premium if above. For Lake Superior ore the basis 55% Fe. Bessemer ore must contain less than 0.45% P, and commands a higher an non-bessemer, the difference reaching 80¢ per ton. For Lake ore, 1916 prices t 70¢ per ton higher than 1915 prices. Eastern ore is often sold on basis of units Prices in 1915 were 6.5 to 7.75¢ per unit for high-grade ore, delivered in eastern ntracts for 1916 are at 8.25 to 9¢ per unit.

ganese ore. A sliding scale is used (5). The higher the Mn content, the higher e per unit. Thus, if an ore contains 40–43% Mn, payment is made on basis of unit; if from 44–46%, 24¢; 46–49%, 25¢; above 49%, 26¢ per unit. The ore not contain more than a certain percentage of P or SiO_2 (say not over 0.2% P, r 8% SiO_2). Above these limits, penalties are levied (2).

GOLD AMALGAMATION

1. Milling Practice

lgamation of gold ores in modern plants is confined almost exclusively to AMALGAMATION, in connection with crushing by stamp battery. PAN AMATION (formerly common), and certain special processes now employed unusual circumstances, will not here be described.

ning and grinding. Ores must be reduced to such fineness that the gold or silver ently freed from gangue to be attacked by mercury. In most mills, after amalga- the pulp is ground still finer, for further treatment by cyanidation or otherwise. in mills, plate amalgamation has been used after tube-milling in preparing ores idation. Crushing is usually by jaw-crusher or gyratory crusher, followed by attery, for details of which see Sec 28, Art 4 to 7. For grizzlies, screens, feeders, mpling devices, see Sec 28, Art 15, 31, and 32; for variations in practice as to size pe of mortars, wt of stamps, and order, height, and speed of drop, see Sec 28, Art 7.

eral principles to be observed in designing and operating the stamp-mill atory to plate amalgamation: (*a*) systematic and accurate sampling of ; (*b*) maintenance of uniform feed, as to amount, size of ore, and (so far ible) as to average values; (*c*) close control of feed water; (*d*) maintenance nstant height of discharge above level of the stamp dies; (*e*) care of bat- reens.

3. Outside Amalgamation

amalgam collects inside the mortar, but less than with inside amalga-
Art 2), since the discharge is lower and the mortar narrower.

le plates comprise: splash plates, deflecting plates, lip plates, apron
d sluice plates. The first two are to regulate the flow onto the lip and
ites, but they are often omitted. As the amalgam caught on SPLASH
hard and does not easily break away, these are preferable to inside plates.
ES are the full length of mortar opening and 6 to 8 in wide; the wider
r. They rest below the bottom of the screen and project over the head
on plate, sometimes feeding the pulp down to the apron plate through a
and distributing box. APRON PLATES are of the full width of mortar,
nnealed copper, and almost always silver-plated. They rest on heavy
ables, which, though adjustable, should be held rigidly and be non-
It has been claimed that by connecting apron plates with the mortar,
g aids the gold to settle on the amalgamated surface, but best practice
is because the amalgam formed is too hard. Amount of silver used in
aries from 1 to 2 oz per sq ft; in some districts as high as 5 oz. Plates
ered after 1 to 3 years' use. In some mills replating is not practiced;
s are put in after several years and old plates are melted down. SLUICE
e rarely used in recent mills. They are about 0.5 the width of apron
d placed in 2 or more sluices or launders, taking the tailings from the
tes. Being narrower and steeper than the aprons, the flow of pulp is
that they catch but little gold.

f plates varies from 1.5 sq ft per ton milled per day (So Africa) to 10
t (western U S). Referred to number of stamps, the plate area may be
10 sq ft per stamp (one 4 by 12 ft plate per battery), the other extreme
sq ft of plate per stamp, arranged in 4 successive rows.

rage for 1 000 stamps in Homestake mills, So Dakota, is 48 sq ft per stamp;
ve mills have 10 sq ft in the first row, 14 in the second, 15 or 16 in the third and
the fourth row. Generally a succession of plates is used with drop between
ough or mercury trap being sometimes placed below the bottom edge of each
ercury traps are advisable, as apron plates may then be kept softer with less
losing Hg or amalgam.

ry traps may be simply transverse troughs, a few inches deep, with
ip discharging onto the next plate, the bottom of trough being provided
ve for discharging collected Hg. A V-shaped, conical or hemispherical
mmoner, receiving the pulp through a pipe reaching nearly to the bottom
verflow going to the distributing box for following plate.

ain mills the amalgam on the first apron plates is first softened by STEAMING. ne by covering the plates with a wooden cover, held a few inches above them, tting steam under the cover. Workmen are in danger of salivation, if they stand lates while being steamed. After the apron plates have been scraped, the traps d of the collected sands, and Hg and amalgam are drawn off through cocks in f traps. Fresh Hg is sometimes put into the traps before starting up again. cted amalgam is removed to clean-up room, which should be provided with onstructed that Hg can be drained from them without risk of loss. Iron kettles or carrying mercury or sands to be treated.

NDS may be treated with additional Hg and water in a clean-up barrel or pan, panned down over the sink to separate the amalgam, the washed sands being to battery. The amalgam recovered here, and that scraped from the splash, side plates, is also washed with addition of enough Hg to make it liquid. Par-on are removed with a magnet. In large mills, the amalgam is worked over in the arrel or pan, with excess Hg; in small mills, it is ground in a wedgewood mortar.

d amalgam is then put in a conical funnel of canvas or heavy unbleached muslin, which the excess Hg drains off; the remaining amalgam is squeezed by hand hamois or cloth, or in large mills by a hand or power press. Chamois is expen-e as it wears out rapidly. Skimmings and dross from surface of the Hg strained ining amalgam are saved for separate treatment. When the ore contains much antimonide or arsenide, the mud settling out of the washings, and the dross from malgam, may be saved and shipped to smelters. Amalgam, squeezed quite dry contains 25 to 40% bullion (the lower proportion when the silver is relatively he squeezed amalgam is finally retorted for distilling off the Hg (Art 4).

4. Retorting and Melting

ts, when of large size, are horiz C-I cylinders built into a brick furnace nd with a pipe from the rear end to an open Hg receiver. This pipe is ed by a larger pipe or jacket, in which cold water is circulated for con-he Hg. The end of the pipe is covered with wet cloth or flannel, dipping receiving pot which contains water.

el of the condensed Hg or water in the pot must never be allowed to rise high cover the end of the pipe; otherwise, if the temp of the retort falls, water may back into the hot retort, causing an explosion. Small retorts are vertical C-I condenser pipe connected to the cover. Retorts are lined with chalk or wood re charging, and the lumps of amalgam are often wrapped in paper, to keep n from adhering to the iron. Vertical pot retorts are filled not over ⅔ full of to avoid having particles of amalgam thrown up into the pipe in case the Hg to overheating. This would clog the pipe, and might cause an explosion.

ging retort. Amalgam is charged in horiz retorts in semi-cylindrical s (usually 4 in number), which are slid into place. The retort cover is th a mixture of fire clay and wood ashes, or clay with a small admixture slimes. Or, gaskets can be used, cut from thin asbestos sheets, heavy first applied to the joint faces. The cover is clamped on securely with nd steel wedges.

g. The retort is gradually heated by wood or coal fire or by gasolene ng to design of the furnace), water running continuously through the er jacket, until Hg begins to pass freely into the receiver. Heat is then d, but should be maintained sufficiently to distil the Hg continuously.

distillation ceases, the heat is raised to a dull red and so maintained for about 0.5 which the fire is allowed to die out, and the retort to cool before it is opened. he final heating the condenser pipe should be occasionally tapped to dislodge the s of Hg. Even with large retorts, distillation should be complete in 5 to 6 hr. ll pots, in say 3 hr.

6. Adaptability of Ores

all gold and silver ores can be treated by cyanidation. In case of gold irides may cause interference, but can be decomposed by preliminary Solution of Au in tellurides by bromo-cyanogen has been successful.

ering conditions. OXIDIZED CU ORES cause high consumption of cyie to ready solubility of oxides, carbonates, and hydrates of Cu. SULf Cu, Ni, Co, Pb, Zn, and Fe react but slightly with cyanide solutions. fere by mechanical inclusion of the Au or Ag, preventing direct attack de, unless very finely divided. Some sulphide combinations of Ag with Pb re only slightly attacked by cyanide, even when finely ground. SOLUBLE :S (especially alkaline sulphides) interfere seriously, both by combina- cyanide and by re-precipitation of the Ag and Au. ARSENICAL AND IAL ORES often cause high cyanide consumption, and sometimes form comaving a strong reducing action in the working solutions. Preliminary may favorably prepare such ores for cyanide treatment. MANGANESE l with Ag often prevents successful cyanidation; a preliminary roast ease extraction, but the cost of this treatment has sometimes been pro- or the results have not been satisfactory. METALLIC MERCURY (often n tailings from amalgamation) is not readily dissolved by cyanide, and, in antities, may assist in precipitating soluble sulphides; present in larger s, Hg causes waste of Zn in precipitation boxes. An ore containing Au and Ag in COARSE PARTICLES, not pulverized by fine grinding, would ılt to cyanide with financial success, because of the length of time re- dissolve the metals; such ores can generally be treated by amalgamaowed by cyanidation of the tailings. At the Nipissing mine, Cobalt, H-GRADE SILVER ORES are amalgamated in a closed tube-mill, in cyanide a similar combination process has proved applicable to other ores also. ACEOUS MATTER, if ground with the ore, increases cyanide consumption ts a reducing action, whereby precious metals are re-precipitated before reach the precipitation boxes.

coming adverse conditions. The refractory nature of an ore can often ome by fine grinding. As yet, chemical analysis alone can not deter- adaptability of an ore.

tory experiments must be conducted to determine: possibility of leaching Au om coarser sands; necessary fineness of grinding: acidity of pulp and amount of ired to neutralize it; amount of soluble sulphides in the pulp and quantity of ate or oxide to be added; amount of cyanide consumed in treating the ore for

time required to effect satisfactory extraction. An ore not a

Nascent Cy. K_3FeCy_6 and BrCy react, without prese
solution, and nascent Cy has greater affinity for precious
as KCy or NaCy. Liberation of Cy by these salts is

$$K_3FeCy_6 + KCy = K_4FeCy_6 + Cy,\ \text{and Br}$$

STANFORD LIBRARIES

tter equation represents the supposed basis of the BrCy process, in which the n presence of Au is stated to be: $BrCy + 3\,KCy + 2\,Au = 2\,KAuCy_2 + KBr$. ions in this process are not thoroughly understood; probably the greater affinity t Cy for Au makes it possible to dissolve Au in such telluride ores as are not at- simple solutions of KCy or NaCy. So far as determined, no bromide of Au is y the use of BrCy.

errocyanides are present in working solutions, $HgCl_2$ may be used to disintegrate formation of double mercuric cyanides, which dissolve precious metals without l O. The cost of $HgCl_2$ limits its use. Certain patented modifications of the rocess claim that an electric current in the agitation tanks aids solution of pre- ials, especially tellurides; the efficiency of such processes is not proved.

gth of solution. The max solvent action of alkaline cyanide solutions to take place with solutions containing between 2 and 5 lb of KCy per a slightly less amount of NaCy. With O present in excess, weaker solu- apparently more efficient. A stronger solution is therefore necessary lation than in agitation treatment, because in the latter air reaches the re quickly and effectively.

ive solubility. It has been held that cyanide solutions dissolve Au and Ag faster or other base metals; it is practically certain that this is only apparent, approxi- ne same amounts of precious and of base metals being dissolved in a given period, ne conditions. Thus, in an ore assaying 20 oz Ag per ton and 0.2% Cu, if all the n equal amount of Cu were dissolved in a given time, there would be 100% ex- of Ag, but only 3.4% of the Cu; this would occur if both metals were in an equally e of division and in chemical combinations attacked with equal ease by the solu- he apparent selective action of cyanide for precious metals is accentuated by the mechanical conditions of precious and base metals are never the same in an ore; als are almost always in coarser particles, and, as their sulphides are less easily . less base metal is dissolved in a given time.

been supposed that presence of certain metals retards solution of Au and Ag, but of such interference the cause is apt to be elsewhere. Thus, in treating certain n New South Wales, in which the Au was contained in Sb_2S_3, it was found that aused no consumption of cyanide except when the solution was too alkaline; in a olution, the only difficulty lay in disintegrating the Sb_2S_3 to reach the fine Au.

ed solution frequently yields higher extractions in laboratory tests; commercially erally found that the increase is not appreciable, and excessive heating of solutions troy part of the cyanide, while also increasing its solvent action on base metals, ailed losses of cyanide. Heating of solutions also expels oxygen, thereby necessi- ncreased aeration of pulp.

mistry of precipitation. Recovery of precious metals from cyanide ns is based, theoretically, on the reaction: $2\,KAuCy_2 + Zn = K_2ZnCy_4 +$ Practically, precipitation takes place only in presence of free cyanide, $KAuCy_2 + 2\,KCy + Zn + H_2O = K_2ZnCy_4 + Au + H + KOH$.

rfering conditions. In actual operation there is always an excess of Zn, s also dissolved by the KCy as K_2ZnCy_4, without necessarily precipitating . In the precipitation boxes, other metals are generally present, forming couples with Zn, which electrolyze the water, liberating O and forming H_2. This combines with free cyanide, forming a soluble double cyanide ly an alkaline zincate). Unless excess of cyanide be present, precipitation $OH)_2$, ZnO, or perhaps $ZnCy_2$, will take place, covering the Zn shavings white deposit, and impeding precipitation of precious metals.

alkali, or excess of cyanide, prevents formation of this white deposit by redissolving precipitate; hence a solution to be precipitated should always contain excess or be strongly alkaline But, the double ferrocyanide of Zn and K, which frequently on the Zn shavings, is but slightly soluble in alkaline or cyanide solutions, and rm enough deposit to interfere with precipitation of the precious metals before the rings have been completely consumed, thus necessitating an earlier clean-up than ise required.

To a slight extent, Al_2O_3, SiO_2, CaO, and Fe precipitation of Au and Ag. Cu interferes still ings. If the shavings in the first precipitation nearly all the Cu can be precipitated before th which the Au and Ag are to be collected. Continued re-use of solutions ultim salts, and even if proper strength of free cya become foul and lose part of its dissolving

It has been advanced that the fouling of soluti cyanides of Zn with other alkaline earths beside base metals and alkalies. It has been proposed t cyanides, and then some hydrate to precipitate al cyanide.

Aluminum dust has been successfully especially when the ore contains considerabl is probably due to the fact that Al does n solution by forming a Cy compound; hence As is avoided.

The reaction is possibly: $6\ NaAgCy_2 +$ $2\ Al(OH)_2$. The $Al(OH)_3$ is redissolved in the reaction, with evolution of H, is: $2\ NaAgCy_2$ $Na_2Al_2O_4 + 4\ H$.

Charcoal, especially soft-wood charcoal, has at time of precipitation is not yet understood, bu are decomposed by reaction with gases occluded or CO, which act as reducing agents. There see soluble double cyanides.

Amalgams of Na and other metals, and amal fications of the cyanide process, to collect precip such processes is the passage of a low-voltage el solution, either before or after separation from t are the Gilmore-Young, Pelatan-Clerici, Riecke trolytic precipitation throws down many of the ba the application of electric precipitation to solution filtering, this advantage is more than offset by th

Cyanicides; loss of cyanide. A cyan either combines with Cy or decomposes a loses its dissolving power. Some loss of Cy without presence of cyanicides. KCy an slowly decomposed by moisture.

Loss by HYDROLYSIS is represented by the rea Cy escaping by volatilization. Loss by ABSORP $4\ H_2O = K_2CO_3 + (NH_4)_2CO_3$. In presence of $KCy + CO_2 + H_2O = HCy + KHCO_3$. In pra above equations are very small.

Losses due to cyanicides in the ore ma chiefly by soluble sulphides, sulphates, and are insoluble in water but react with cyanide in oxidized or semi-oxidized ores, are apt t cyanides of Cu or Fe and K or Na. Free aci obviated by maintaining sufficient alkalinit

STANFORD LIBRARIES

ores, K_2S or Na_2S is formed; if then the cyanide solution be allowed to ak, these alkaline sulphides may accumulate sufficiently to reverse the and re-precipitate Ag as sulphide; or the alkaline sulphides may oxidize hates, or may form thiocyanates, thus consuming either the available O y, and decreasing the dissolving power of the solution.

Fe_2SO_4 and $CaSO_4$ decompose alkaline cyanide solutions; arsenates of Fe and als also react with Cy solutions and destroy their dissolving power. While FeS_2 react with cyanide quickly, nor to an appreciable extent, ferrous sulphide and nd ferric sulphates combine actively. Sulphides of Cu and Zn are practically ed by cyanide solutions, but their carbonates, oxides, and sulphates react rapidly.

8. Outline of the Process

ery of Au and Ag by cyanidation consists broadly of 4 operations: (*a*) ion of the ore; (*b*) solution of precious metals; (*c*) separation of dis- netals; (*d*) precipitation and refining of product. After preparing an pulp may be classified into coarse and fine products, SANDS AND SLIMES, ay be treated separately; or, all the ore may be ground very fine and together by the ALL-SLIMING process. Variations in preliminary treat- ll be described in general outline, but many ores present problems re- special modifications.

s, when treated separately, are usually charged into vats or tanks where submitted to washes of cyanide solutions, which are then separated from ed pulp by filtration, and the precious metals in solution are precipitated.

es (pulp passing a 200-mesh screen, or, in some cases, 80% of which will -mesh) can be treated by cyanide solutions, followed by settling and tion; or can be agitated with a cyanide solution, mechanically or by ed air. The pregnant solutions can be separated by decantation after or by passing through a filter-press, their subsequent treatment being e as for those resulting from sand treatment.

ipitation. After solutions have passed through a filter-press (or have anted), it is sometimes necessary to clarify them further before allowing pass to precipitate. In most cyanide plants clarified solutions are ver Zn shavings to precipitate the metals.

e, use of Zn dust for precipitation is increasing, and quite recently, of aluminum e barren solution then passes through a filter-press to separate it from the precipi- or Ag. Other precipitation methods are by electrolytic action, and by charcoal. te is then dried, melted with fluxes, refined, and cast into bars.

al processes and modifications. COMPOSITE METHODS. Many attempts have de to dissolve and precipitate in the same vat, chiefly by using low-voltage electric ; none has been entirely successful. Variations occur principally in the type of which must be so selected as to present a sufficiently large surface, to which the d metals will not adhere too strongly, and will not produce too base a bullion. on, tinned iron, Al, amalgamated Zn or Cu plates, Hg and amalgams have been A fundamental objection to such processes is that deposition of other than the metals on the cathodes occurs, thereby preventing further precipitation. The process, used in Australia, substituted a weak solution of HCy for cyanide, being formed, to the extent of 0.05 to 0.1%, by action of H_2SO_4 on KCy. After of the metals, limewater was added to neutralize before precipitation by Zn. cess was found to be inapplicable to ores containing $CaCO_3$.

lgamation with cyanidation. When Ag and Au occur as metallic par- hese are sometimes too large to be dissolved by cyanide in the allotted In a tube-mill, however, the particles are so flattened that they can be ed in relatively short time. One of the chief disadvantages of plate mation, after battery crushing and before tube-milling, is that the fine

No 2, and about 17% No 1 size. Subsequent
largest or No 3 size. If the pulp is fed
very coarse, the proportion of coarse
pebbles may be increased.

Feed should be dewatered so as to leave 30 to 38% moisture in the pulp, at which consistency the best grinding is secured. Tube-milling can generally be so regulated that all the pulp discharged can go direct to the agitation or other cyanide treatment; but in large mills it may be advantageous to classify after the first tube-milling and return the oversize for regrinding in the same or other tube-mills.

Hardinge conical mill operates like the tube-mill, but occupies less floor space and some economy in power is claimed (Sec 28, Art 10). The theory of its increased effic is that the pebbles of larger diam seek the largest diam of the cone, and there grind the coarsest ore, while the smallest pebbles do the finer grinding near the discharge.

Substitutes for pebbles. Where hard quartz is available, about the size of coarsest pebbles, it may replace grinding pebbles wholly or in part. This is advantageous in saving the cost of pebbles, and because the quartz itself generally carries recoverable values in Au or Ag. Consumption of quartz fragments from the mine is about 3 to 5 times that of Danish pebbles.

Lining of tube-mills may be of SILEX BLOCKS set in cement, or of steel ribs which hold part of the pebbles ag upon which grinding is done. This is know

bars and grind on the surface of the plates. El Oro lining is the cheapest to t and maintain, and the quickest to replace.

harge from tube-mills is through an opening in the trunnion, or through discharge receiving the ground pulp through slots in the cylinder head-Trunnion discharge generally results in finer grinding of the heaviest particles than when the discharge is through slots. Within certain decrease of moisture in the charge increases the mill capacity.

mills resemble tube-mills; they use steel balls in a revolving cylinder, but e through slots between the lining plates and then through an outer They are driven more slowly than tube-mills, admit of coarser feed, use ver, and the wear is less, but they do not grind so fine.

of mills. A tube-mill 4.5 ft diam by 12 ft long requires about 45 hp ; for a mill 5 by 22 ft or 5.5 by 18 ft, as much as 90 hp must be on to start. After attaining full speed the power decreases 30 to 40%. o 5 ball mill about 25 hp is required for running; No 8 mill, about 55 hp. Hardinge mill takes 15 to 20 hp; 8-ft mill, 30 hp or more. The above vary widely with rate of feed and speed of revolution.

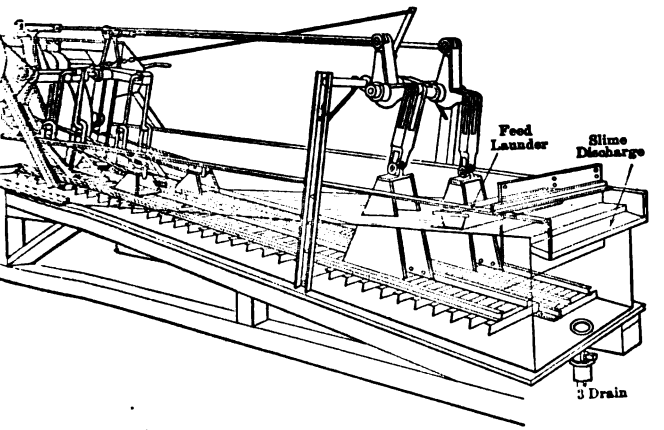

Fig 3. Dorr Duplex Classifier (Model C)

t of tube-milling varies greatly, according to cost of power, labor, and s, and is dependent also on character of ore, size of feed, and fineness of ig. Many mills show costs between 9 and 18¢ per ton. Under favorable ions, 12¢ is an aver figure, where power represents about 25% of total cost, 20%, and pebbles and repairs 55%. (For details of fine-grinding mills, c 28, Art 8–11.)

ssifying. The separation of coarser sizes from the finer, as preliminary king 2 sizes for separate sand and slime treatment, or for removing the ntly fine slimes from the material to be ground in the tube-mill or to be ed as oversize, can not well be done by screens, and classifiers must be used.

zkasten, cone, and hydraulic classifiers generally cause the introduction of too much when they size effectively, and modern tendency is to use mechanical classifiers. classifiers have large capacity when the proportion of slimes is great, but do not

es 4 radial arms with short rakes, which in revolving slowly move the settled ards the central discharge. Bottom of tank may be slightly conical, conformnation of the radial arms, or, if the tank be flat, the accumulated slimes will soon nical bottom surface. Feed enters the tank through a short central pipe, dislow the overflow level, to avoid surface currents. About 0.25 hp is required to This machine has also been used partially to decant very rich solutions from nes that are sticky and would filter slowly (see Sec 28, Art 18).

10. Sand Treatment

. **Sands,** after separation from slimes, are charged into tanks fitted -bottoms, consisting of a grating overlaid by cocoa matting and canvas. s a layer of sand is charged on the filter proper, and over this is spread to limit shoveling of the tailings when the tanks are discharged.

grating is arranged to insure free circulation of the filtered cyanide solution on ottom towards the solution discharge pipe; there should be always enough origh the supporting frame of the bottom grating to allow all parts of the tank drain freely towards the discharge. The canvas, which is placed over the cocoa s calked into position around the edge with rope; it is also calked around the ate when the tank is discharged through the bottom by shoveling, by sluicing, chanical excavator.

of tank depends on fineness of sand and amount of slime carried. With clean d, tanks may be deeper; in practice, depth is 6 to 10 ft. Depth is decided upon rimenting with the ore to be treated, to determine the RATE OF PERCOLATION. should be between 1 and 3 in or more per hr for satisfactory results and the pulp so classified that the resulting sands should have at least this rate of percolation. **of treatment** being determined, and rate of percolation and depth of tank de- **area of tank** is made such that one or a number of tanks will hold approxie day's mill run.

tion. The tank is generally filled with wet pulp from the classifiers, stributed by some automatic device. This usually consists of revolving s with perforations, or modification of this device. After filling, the drained, and, if crushing has been done in solution, the solution is stored until it is high enough in precious metal content to be effectively pre-

After the first draining, the first and generally the strongest mill solun into the tank to cover the charge. Practice varies as to admitting on at top or bottom of the tank.

ents determine the strength and number of the successive cyanide solutions used hing with clear water. A variation of practice is to use downward percolation; ly drawing off the cyanide solution from the bottom, and adding fresh solution until the desired extraction has taken place. But this practice does not aerate well as intermittent flooding and draining of the charge, which generally gives traction.

ary precautions for percolation of sands: charge should be evenly distributed s and free from slimes which pack and prevent passage of solution.

ions of practice in percolation of Au ores show following range: drainter from wet charged tank, 8 to 18 hr (aver, 13 to 14 hr); leaching, 12 ver, 15 hr); washing, 16 to 22 hr (aver, 20 hr). Most mills use 1 strong ak-solution treatments, and 1 with wash water. Some mills have intraction by forcing air up through the filter bottom before each appli- solution. Pressure used is only sufficient to aerate slowly without hannels in the sands.

rging the tanks by shoveling costs most, and is used in small plants er is scarce. Sluicing is cheapest, and is used where water is plentiful. al excavators (radial arms, carrying circular plows that are lowered ands and move them to the central discharge door) are high in first

ion of pulp. To the d pulp charged in the ; tanks enough stock solution is added to ıe pulp to the required ıcy, at the same time ing the proper strength de in the charge. Dilu- the pulp depends upon r of the slime; thick ime requires greater dilution for prompt extraction. Practice varies from lution to 1 part dry slime by wt, to 4 or 5 parts solution to 1 part dry Accompanying table is useful in dealing with the sp gr of pulps; it is a sp gr of 2.5 for dry slime.

rliate values in the table may be interpolated. In practice, it is usual to take f the thoroughly agitated pulp in a weighed flask of known capacity, and from t of the pulp calculate the sp gr, the other data being obtained from the table.

gth of solution. The amount of cyanide in the solution which forms the he agitation tanks is determined by experiments on the ore, and varies n different places. The strength may be expressed in terms of lb or per KCy, it being usual to figure back to the basis of KCy even if NaCy be n general, for Au ores, from 0.05 to 0.25% KCy covers the range of of solution. For Ag ores, the range is from 0.25 to 0.50%.

battery crushing or tube-mill grinding has been done in solution, the strength of ed is generally much lower than that named above, and, to bring the pulp up to percentage of cyanide, a stronger solution is added in the agitation tanks to the pulp; or, if the pulp reaches the agitation tanks already sufficiently dilute, anide are dissolved in the charged tank when agitation commences. At the same proper amount of Pb $(C_2H_3O_2)_2$ is added, which is generally done by suspend- burlap bag in the charge, containing Pb $(C_2H_3O_2)_2$ corresponding in amount to ed for the treatment of the number of tons of dry slimes in the tank.

arge should also be tested for protective alkalinity, though the proper amount insure this is generally crushed with the ore in the battery, or milk of lime is the charge in the tube-mill.

rouble has been experienced in air agitation, due to excessive use of lubricating compressor cylinders. Some plants use soapsuds or graphite lubricant for ers, and claim that extraction is thereby increased.

strellas mill No 1, Michoacan, Mex. Sand and slime treatment. Extraction es, 71% Ag and 92% Au; from sands, 68% Ag, 90% Au. Cost, $1.55 per ton.

tersrand, So Africa. Early practice. Free gold ores, sand treatment (1894). raction, 78%. Milling and cyaniding cost, $2.20 per ton. Simmer Deep (1909). ore, sand percolation and slime decantation. Extraction, 90%; cost, $1.09. d (1910). Sand and slime treatment. Extraction, 92%; cost, $1.33. Gelden- 1). Grinding and cyaniding concentrate, agitation, and continuous decantation. n, 98%; cost, $6.32.

rlie, Australia (1909–10). Free gold and telluride ores. Roasting, amalgama- cyaniding by agitation. Extraction, 95%; cost, $2.40 per ton.

ealand. Treatment of complex sulphide concentrates by fine tube-mill grind- gitation, and filter-pressing. Extraction, 96% Au, 93% Ag; cost, $6.25 per ton.

17. Cyanide Poisoning

s and symptoms. Cyanide poisoning may result from taking cyanides y or from inhaling HCy gas. CHRONIC form of poisoning, due to long to the fumes, is manifested by disturbance of vision, pain in the fore- l in region of the heart, palpitation, difficult respiration, vertigo, cough- attacks of suffocation. Symptoms of ACUTE poisoning, as when taken y, are, besides the above, constriction of throat or general contraction of and dilated pupils. Face becomes pale and bloated, nails blue, some- thing at mouth. Convulsions occur, followed by coma, and death om asphyxia.

ment. If poisoning is caused by breathing fumes, and the case is not elief may be afforded by breathing ammonia fumes and remaining in . If gas has overcome the patient, a number of hypodermic injections % solution of H_2O_2 may be made, or a 10% solution of it given internally.

al respiration may be resorted to; or, if available, O alone may be administered. nics of ether, strychnine or whisky are given to prevent collapse. If the cyanide **swallowed,** an efficacious antidote is $Fe(OH)_3$, which must be freshly prepared.

wheat No 4.....	3⁄₆₄	3⁄₃₂	.....	.....	.....	.....

f market sizes is about as follows: lump, for locomotives; steamboat, for nace and forge; broken, for domestic furnace and forge; egg, stove, and nut, for furnace and range; pea, for domestic furnace and range, and steam boiler; at, rice, and barley, for steam boiler. Buckwheat No 4 is a recent product, er boilers at some collieries, to replace rice and barley.

pared sizes" is the trade name for: broken, egg, stove, and chestnut, which e about 65% of the total production. General demand for lump and steam- mall and decreasing. Probably these sizes will not be produced in a few years; be "broken down," as is done at present, when there is no demand for them.

m sizes" is the trade name for: pea, buck, rice, and barley. These are the ion resulting from the mining and handling of a brittle or laminated material, ot especially desirable.

f-mine is the unsized mixture of coal and impurities, as dumped into the According to method of loading cars in the mines, it may be divided into:

1. Hand loaded (as in flat workings), containing lumps up to about 150 lb ively free from impurities in coarse lumps.

2. Chute or steam-shovel loaded (as in steeply pitching seams or in strippings), g lumps up to about 2 000 lb, and frequently wet and dirty.

ities in run-of-mine vary with character of seam, and with method of loading. hand loading they may be partly removed, but in chute loading the entire cluding all impurities and foreign matter, as clay, top and bottom rock, and imbers, must be loaded into the car. Impurities in Class 1 usually range from to 25%; in Class 2, about 10 to 55%.

dard of preparation designates the percentage of over or under size mpurities allowed in each size of coal (Table 2). BONE (mixed coal and defined as containing between 40 and 65% carbon.

car yield is a local term, usually indicating number of long tons of marketable pped from the mines for every 100 cu ft of mine car capacity dumped. This ment, for hand-loaded cars, is somewhat misleading. For chute loading, the city is figured at its water level; to this, for hand loading, is added a volume the horizontal area times 6 in. The added height of 6 in, above top of car, is PPING. Should the topping exceed the required 6 in, no account of it is made ating mine car yield, nor is it practicable to do so. The exact method would be mine car yield on the weight of loaded mine car; but this would complicate nt rates paid miners, lead to disputes and labor troubles over amount of allow- urities in each car, and violate the award of the Anthracite Strike Commission of the subsequent agreements between operators and their employes. The present admits a fair comparison between mines operating under similar conditions. A

the mine cars, with prices at mines, as of Feb, 1913, assuming 1 000 tons erial delivered to breaker. (War prices are not considered.)

le 4 gives percentage of shipments of each size made by preparation of oo tons of run-of-mine in Table 3, and the average and total amounts d, assuming each size to contain the allowable percentage of impurities, able 2. Each size in Table 4 contains no under or over size, and if the um amounts allowed (Table 2) were put into the highest-priced sizes, erage price per ton would be increased. In practice it is impossible to coal without under or over size. Hence, tests are made, and the screen ncreased or diminished, so that the greatest allowable percentages of over er size are carried in the highest-priced sizes; or the screen mesh is ad- to produce maximum amount of sizes required to supply the market. y all the barley coal, and sometimes part of the rice, is required for the boiler fuel, so that the average price per ton does not generally include izes. Fuel burned at the colliery approximates 5 to 10% of total pro-

. In Table 4, Class 2 shows a loss of $779.86, compared with Class 1, efly to difference in amount of impurities in the run-of-mine (Table 3). ould also be a further financial loss due to increased preparation cost in g and removing the higher percentage of impurities.

king-down large sizes. If the lump, steamboat, broken, and egg m 1 000 tons of Class 1, run-of-mine, Table 4, were broken down to stove, l the steam sizes, the approximate shipments in tons and amount realized e as shown in Table 5. The saving, $75.28, is attributable to the effi- f the slow-speed rolls used. With high-speed rolls, of poor design or ll teeth, the efficiency would usually be low, and the breaking-down ause a loss due to high percentage of pea and smaller sizes made, which pproximates 20 to 30%, as compared with 13.8% obtained in Table 5.

3. General Method of Preparation

line is the same for the 3 classes of breaker. Coal is dumped into receiv- pper and fed automatically, or by a hand-operated gate, on to the dump s at the top ("head") of breaker. Lump, steamboat, and broken are rom the run-of-mine (always the first 2 sizes, and often the broken also) e cleaned of impurities by hand-picking. This cleaned coal is the "pure- product, and is handled separately, except in a Class *C* breaker. It re- no additional attention except to be broken down, when necessary, sized elivered to loading pockets. The prepared and steam sizes from run-of- including the broken coal, when not handled with the pure coal) are "mud-screen product." This gravitates from dump screens to sizing creens, from which each size flows to its respective mechanical cleaner en runs to storage pockets. In Class *A*, the pure and mud-screen coal xed and go to same pocket. In Class *B*, these sizes are stored in sepa- ockets, when dry coal is desired or practicable; otherwise they are washed r and mixed. In Class *C*, the sizes are always mixed.

STANFORD LIBRARIES

Breaker refuse of slate, bone, or rock, as cleaners in all classes of breakers, is convey central point for final disposition, for which (*a*) Refuse is returned into the mines to fill coal. This method, called SILTING, involves large pieces of refuse, from broken coal and la material, together with all other breaker ref machine, reducing entire product to 0.5 to 0.7 mine through pipes (Sec 10). (*b*) Refuse BANKS, by chain or belt conveyer, or by du haulage, or by hydraulicking all or part of it,

Silting should be given preference and is super to the stability of the remaining mine pillars a surface disposition of refuse is necessary, the hyd topography of the region permits, and there is plen licking is not practicable, the conveying system i jacent to breaker is available. Banks can be can extended in length by added horizontal conveyin around top of bank. To eliminate trouble from refuse is crushed to about egg size. When bre of dump cars is advisable, advantage being that breaking.

The pure broken coal from crushe from picking table and gravitate with it to its p going to the re-breaker rolls and the remainder t go to the re-breaker rolls. The pure egg coal re-breaker rolls, or may be divided in the sam product from re-breaker rolls flows to a broken pocket, while the undersize mixes with the prod above the re-breaker rolls, and the combined ma arranged to size pure egg, stove, nut, and pea coa

MUD-SCREEN PRODUCTS, egg, stove, nut, and p usually), contain impurities in excess of that sta removed, to keep within the allowable limit for from its sizing screen to a mechanical cleaner or s impurities, the coal flowing to its pocket and the sionally the mud-screen buckwheat requires clea similar manner; when such cleaning is unneces

ley are mixed with the corresponding pure-coal sizes and delivered to the buck-ice, and barley screens, where each size is separated and delivered to its pocket, e fine material through the barley screen goes with the refuse. If it is de-make buckwheat No 4, an additional screen is installed. While loading into shipment, the fine dust and screenings made during preparation are removed by the coal over punched steel plates or woven-wire screens, LIP SCREENS. Lip-oduct is elevated to the sizing screens to be re-sized and returned to the pockets. ading, the coal is inspected for size and purity, in conformity with Table 2. s in this inspection, it is condemned, unloaded, and elevated into the breaker and d.

gn in Fig 1 contemplates an ideal breaker. For 1 500 to 1 800 tons apacity, total height above loading track would not exceed 115 ft. Coal through breaker by gravity, thus eliminating conveyors and elevators. nveyor only would be required to handle the lip screenings and condemned Roll tests show highest percentage of prepared sizes when breaking only ne size to the next smaller; that is, steamboat to broken, broken to egg, stove. With this arrangement the breaker would require 4 sets of rolls, creasing the height, unless the re-broken material is re-elevated, but the e in prepared sizes would not warrant this installation. In practice, the oat and broken screens, set immediately below crusher and re-breaker espectively, are omitted; because a sufficient percentage of steamboat lly made from the picking table, in proportion to the other sizes shipped uired for the market, and the crusher rolls will break lump or steamboat into broken without oversize of steamboat, which would condemn the . Sufficient egg coal can be made above the re-breaker rolls, and any e from them will be carried by the stove. Mixing the pure and mud-prepared and smaller sizes is advantageous. When pure coal from the is broken down, each size will usually carry less than the percentage of ties stated in Table 2; hence, the mud-screen coal from the mechanical rs may contain an excess of impurities without causing the resulting re of pure and mud-screen coal to exceed the allowable percentage.

mple. Assume prepared sizes from run-of-mine to be 130 tons egg, 220 tons and 250 tons nut. Percentage of impurities in each size from run-of-mine is 14%. l coal, 45% is pure and 55% is mud-screen coal, all impurities being removed from re coal. Percentage of impurities allowable in mud-screen coal, without causing on of mixed product, is as follows:

130 tons egg × (100 − 14%)	= 111.8 tons clean coal	
111.8 × 0.45 (%)	= 50.31 "	pure coal
111.8 × 0.55 (%)	= 61.49 "	mud-screen coal
50.31 × 0.04 (% of impurities, Table 2)		= 2.0124
61.49 × 0.04 " " "	" "	= 2.4596
Total tons of impurities allowed,		4.4720

2 ÷ 61.49 = 7.3% impurities in mud-screen egg before mixing with pure egg.

same manner, mud-screen stove may contain 12.7% and mud-screen nut may n 18.1%, or in this particular breaker, it would not be necessary, theoretically, to e any impurities from the nut, as the mud-screen product, mixed with the pure would be within the limit of allowable impurities. Impurities in run-of-mine often the average, and to handle the varying product the cleaners are usually installed, hough figures indicate that they are not required.

5. Class B Breaker

tails of preparation (Fig 2). This type provides for separate shipment re and mud-screen coal of all sizes, except buckwheat, rice, and barley. ral method of preparation is practically the same as for Class *A*, except

-mine is elevated to a receiving hopper at head of breaker, from which
l mechanically or by hand into a bank of 4 screens which size lump,
oat, broken, and egg. Lump and steamboat are "skinned" on picking
that is, only a part of the rock is removed. After being broken down
zes are mixed with the mud-screen coal and prepared with it. Pure
id steamboat are crushed to broken in crusher rolls and flow to a bank
reens, which size broken and egg. Broken coal gravitates to the re-
rolls, and is reduced to egg or stove and the smaller sizes, going thence
tral storage pocket. Egg coal gravitates direct to central storage pocket,
ixed with the broken going to re-breaker rolls. Mud-screen broken and
usually run over preliminary mechanical cleaners. These sizes are
from the cleaners in the same manner as the pure broken and egg, and
n the central storage pocket. The unsized mixture of pure and mud-
oal is fed mechanically to a bank of 5 screens, sizing egg, stove, nut,
l buckwheat, each size gravitating to its respective JIG STORAGE pocket.
ocket is a reservoir for the jigs, accumulating coal during rush periods;
essary because jigs are operated at a fixed capacity. The jig removes
t impurities to make marketable coal, and from it each size flows to
pockets. When the jig is emptied, the hutch product, containing nut
l smaller, is washed over a JIG-SLUSH SCREEN, of a size to remove only
l smaller than barley, the oversize being re-elevated to the central
pocket. Rice and barley falling through buckwheat screen are handled
ss *A* or *B*. Sized coal is loaded and inspected as in Class *A*; lip screen-
condemned coal are re-elevated with the jig-slush-screen product.

ntage of bone coal in run-of-mine is usually small, and the sized products will
the bone in a seam, if the rock is eliminated (Table 2). This mode of handling
recommended above all others. When the bone percentage exceeds total allow-
e and slate, bone is handled separately, and the preparation here is identical
ss *A* or *B* breakers. A three-part separation is made of the run-of-mine on the
tables: coal, bone and impurities. Re-breaker rolls reduce this material into
tove and smaller, the broken-down product being mixed with the pure coal sizes
roportions which each will carry. Prepared-coal mechanical cleaners also make a
rt separation; bone from egg and stove is broken into nut and smaller, or the
ve, and nut into pea and smaller, and then screened and mixed with the sized
ng to pockets. Modern methods usually disregard bone coal, and make no
rovision to handle it, except to consider very poor or heavy bone as an impurity
d pick it into refuse from the large sizes.

coal, characteristic of certain seams, as compared with the more usual cubical
when occuring in sufficient quantity in mud-screen prepared sizes, is removed by a
picker before going to mechanical cleaner, thus avoiding the difficulty in removing
es from a mixture of cubical and flat pieces in a mechanical cleaner. Flat coal
its own mechanical cleaner, and the clean product is mixed with cubical coal
oing to pockets. The quantity of flat coal is often sufficient to spoil the appear-
prepared sizes, when loaded. When this occurs, part of the flat coal is removed
ken into smaller sizes.

7. Breaker Structures

es: (*a*) all timber; (*b*) all structural steel; (*c*) all reinforced concrete;
el base, timber superstructure; (*e*) reinforced-concrete base, timber super-
ure; (*f*) reinforced-concrete base, steel superstructure. To determine best
adopt, divide estimated cost by total estimated tonnage, and to quo-
dd estimated preparation cost plus yearly maintenance charges per ton
l.

reciation. TIMBER STRUCTURES. For dry breakers, depreciation depends

sification. There are 3 groups, the operation of which depends on: ference in specific gravity; (*b*) difference in coefficient of friction; (*c*) ce in shape of fracture.

Plunger and pan jigs. Plunger types are generally preferred. A jig an overflow discharge breaks less coal than one equipped to elevate m jig-tank mechanically. The latter are largely used when jigs are to ed low down in the breaker, to save height. Advantage of a jig is that consistently treat a mixture high in impurities, yielding a product to market requirements, and discarding less than 4% of coal in the refuse. ful operation depends largely on jig tender's skill, and on the size of coal utomatic jigs are now being introduced. Breakage loss may vary up according to size of coal treated, and jig construction. Average maxi- rcentage of impurities to be successfully eliminated by a jig should not for egg, 25%; stove, 30%; nut, 35%. Capacity per hour: egg, 4 to stove, 4 to 12 tons; nut, 5 to 12 tons; pea, 6 to 15 tons. Usual sizes of rforation: for egg, ⅞ in; stove, ⅞ in; nut, ⅝ in; pea ⅜ in; buckwheat, (For further description and illustrations of coal jigs, see Sec 35, Art also, for jigging of ores, Sec 28, Art 20 and 21.)

14. Location and Requiren

Irregularities of market for all sizes of an
with continuous operation of the mines, have le
direct control of the mining companies. Stora
venient for traffic. They comprise the whol
amounting to approximately 6 000 000 long t
retail storage yards, in cities and towns throug
usually vary from 1 000 to 3 000 long tons,
sumers' coal bins are the great storage units
not under control of the producers, customers
reduction of price, on April 1st of each year, an
after added each month until the normal is rea

Seaboard plants are situated at or
deliveries to consumers, and less interfe
labor difficulties. Disadvantage: capit
charges.

Local plants are situated in or near
short haul from the mines and quick rele
shortage); low freight charges on coal sto

t. **Disadvantage:** unavailability during labor troubles or interrupted portation.

erior plants are on or near the Great Lakes, especially at Buffalo as a ship- oint, and at receiving points in Minnesota, Wisconsin, Illinois, Canada, few railroad points at important junctions west of the Alleghanies.

l storage plant should fulfil the following conditions: (*a*) Production of mini- reakage in stocking and reloading; (*b*) separate storage of each size and in varying ties; (*c*) rapid handling in storing and reloading (docks, on the Great Lakes, ng coal by steamers, should have large unloading and stocking capacity, as quick h of boats is desirable; (*d*) screen house to resize all coal from storage; (*e*) sep- storage for screenings and facilities for resizing them; (*f*) arrangements for re- and screening more than one size at a time; (*g*) loading facilities for both box ondola cars; (*h*) covered storage when in regions subject to extreme cold and snows; (*i*) facilities to handle frozen coal, especially at plants receiving wet coal he mines or at uncovered plants; (*j*) ample railroad classification yards; (*k*) am- ckage through plant, operated by a car haulage system; (*l*) loaded and empty les; (*m*) minimum danger from fire; (*n*) design permitting enlargement; (*o*) low st per ton of capacity, and minimum operating cost.

zen coal is most efficiently thawed by hot water; steam jets are of little use. should be ample provision to handle the drainage, which contains much fine dirt.

eration of storage plants is very irregular. Night and day rushes, in ding or reloading, are often followed by long periods of inactivity, with ant either full or empty. Low operating cost, when the plant is working, e offset by high fixed charges during idle periods.

15. Classification of Storage Plants

h of the two general classes, wholesale and retail, is sub-divided into nechanical and mechanical.

nechanical	
ocking on surface	Reloading by hand, yard reloaders, or steam shovel
ocking on surface from trestle	Reloading by hand or yard reloaders
ocking on surface from trestle	Reloading by tunnel, with cars or conveyers to a screen house, with or without yard scrapers
ocking from trestle into bins	Reloading from bins into cars or wagons over lip screens
ocking from trestle on hillside	Reloading by hand, dock scrapers or by hydraulicking
anical	
ocking by elevator and conveyers into bins	Reloading by tunnel as in *C*, or direct into cars or wagons, as in *D*
ocking by cable railway and dump cars into bins or on surface	Reloading by hand, tunnel, or from bins, as in *C* and *D*
dge system. Stocking by truss trimmers in conical piles	Reloading by swing conveyers, or pivotal reloaders with inclined conveyers to screening towers
ocking on hillside by traveling cantilever trimmer	Reloading by gravity and hydraulicking
ocking on surface by traveling trimmer	Reloading by longitudinal and cross tunnel conveyers, fed by gravity and traveling reloaders, delivering to screen house
ocking by surface cable cars, operating on traveling tramways	Reloading by tunnel conveyers to screen house
ocking by grab buckets, operating on traveling or fixed tramways	Reloading by grab bucket and conveyers to screen house

STANFORD LIBRARIES

16. Application and Outline of the Diffe

A. Limited to temporary storage of steam sizes level surface, laying tracks on the accumulating sto the storage grows. Reloading with steam shovel o edge of pile, or by hand. Only one size can be sto is excessive, no screening is possible, and operating almost prohibitory.

B. Commonly used for small retail yards, when Consists of a trestle, the height of proposed pile, Sizes are separated by partitions. Reloading by Only hand screening is possible. All sizes may be to high drops in stocking. Operating cost, appro advantage.

C. Occasionally used for large storage, wh more expensive plant. Stocking is done by t tunnel under the storage pile. Reloading ga to a belt or scraping conveyer, which transf point or screen house. Lip screens at loading ing when loading cars. Screenings are collect transferred by hand to a screening storage. A mately 60% may be reclaimed by gravity, t hand or yard scrapers, with a partial screeni is excessive, due to high drops in stocking a in reloading. High first cost, imperfect sizin mating 10¢ per ton are the disadvantages of t

D. For large retail storage plants, for whol interior plants loading boats or steamers. C road tracks, from which each size is dumped i is direct into cars or wagons, which pass und gates in each bin feed the coal over lip screen may be collected in dust boxes under the s conveyers to screenings storage. ADVANTAG quantities, and reloaded by gravity; can unl at the same time; partial screening. DISA due to high drops in stocking and drawing co imperfect sizing; operating cost approximat approximates 5¢ per ton handled.

E. For large storage, of pea coal and small slope of 25° to 30°, at least 300 ft wide, with a this slope to a level surface for tracks; reason the storage hill and down again. Coal is sto hill, and avalanches down the hillside until a a level space at bottom. Reloading is throug layer retained by the wall and lying above gravity to reloading gates. It is usual to rel scrapers, swing conveyers, or by hydraulick Fixed screens in front of loading gates rem which may be conveyed by cars or conveye house. Lip screens not used on sizes small sizes are separated by partitions, made mova ties. Entire hillside should be protected b intermixture of dirt. Operating cost approxi

F. For small retail storage, where location prob an easy grade. May be developed for large storag

R cars into a receiving hopper, which feed into an elevating and scraping or carry-nveyer, transferring coal to storage bins. Automatic shovel unloads box cars into ng hopper. Reloading is direct into cars or wagons, through gates with lip screens delivery chutes, the screenings collecting in a box underneath. Lowering chutes graphs in each pocket reduce high drops when stocking. Stocking conveyer may e storage building, the lip screenings gravitating from the storage box to the lower the conveyer; then re-elevated and discharged into a screening bin. The space en under side of pockets and the surface may be used for storage by stocking through in bin bottom. This stock coal is chuted to the lower run of the conveyer and ed to pockets.

For large storage plants or retail yards; especially to transfer water-ed coal to storage or direct to screen house. Consists of a cable or gravity n car, traversing bins or a trestle over a surface storage floor, and dumping desired points. Reloading is by hand, or tunnel, with conveyer. Method eening is similar to that of *C* and *F*, or when well-sized coal is desired, it be re-screened in a separate screen house, as with *K*. Low in first cost peration, readily adaptable to extension and for covered storage. Break-nto pea and smaller, may be as low as 8%, but is generally higher.

Dodge system, used for large storage, consists of storing on the surface nical piles by a trimmer truss supporting a flight conveyer. A unit has mmer trusses with track hopper, one central reloader, and a screening , with loading tracks and scales. Loaded cars are dumped into a receiv-opper and fed into the trimmer conveyer, which is built on a catenary from under the hopper to meet the incline of trimmer truss. Coal is arged at apex of the growing pile, through bottom of conveyer trough. om of trough is a flexible steel ribbon, which is pulled up to vary the dis-e point as height of pile increases. Reloading is by a pivotal reloader ed between the two conical piles), which carries a flight conveyer on its Reloader travels on a curved track, and is drawn against the edge of ile by wire cables winding on drums placed on the reloader. Coal is drawn e pivotal point of reloader, where the conveyer is inclined, and is carried reening tower. Shaking screens in this tower size the coal and deliver it t into cars. Screenings are collected in a hopper and transferred to a n house for sizing. Driving engines or motors are located near reloading r. Trimmer conveyers are usually rope-driven, to minimize weight on . This type may be readily enlarged by adding additional piles. OPER-G COST, which averages 5¢ per ton handled each way (total 10¢), is gov-d by the activity of the plant. BREAKAGE in the prepared sizes varies approximately 6% for egg to 2.5% for nut.

is type requires large area in proportion to its capacity. A 120 000-ton plant covers 00 sq ft, as compared with 105 000 sq ft for a modified Dodge plant, not including s. Practically all the coal is reclaimed by machinery. A modified Dodge plant lly has fixed trimmers in a storage building, with bulkheads between piles. Reload-s by a tunnel conveyer under each pile, delivering each size to its respective screen e, and thence to a storage pocket to be loaded into cars.

For large storage plants, especially for steam sizes. Consists of a side e, as described under *E*, and single-track trestle with continuous bin chutes fficient height to permit feeding into a traveling cantilever trimmer, by ch the coal is elevated and discharged onto storage floor. Cantilever trim-comprises a platform, mounted on trucks, traveling on a broad-gage k, parallel to dumping trestle. It carries a cantilever truss, and a scraping eyer with a movable trough bottom, which permits discharge at any de-d point. To increase capacity and prevent stored coal from flowing back rimmer track, a bulkhead may be erected between storage floor and track, ading as in *E*.

between sizes, or by leaving valleys between them
Increase in speed of stocking is accomplished by
is especially adapted to irregular areas, using fi
covered storage. Operating cost approximates
sizes varies from 8 to 15%, due to high drops in

L. For large storage, especially at interior
which receive coal by water. Grab buckets
used for stocking. Storage floor parallels th
or more bridges, which may be propelled a
one end of floor to the other. Bucket is sus

across the bridge on a track hung from the lower chord; a hinged boom, tracks matching those on the bridge, extends over the vessel so that the t may unload direct from boat into storage. Reloading may be done by l conveyers, or a conveyer may be placed at rear of storage floor, to re- coal from the grab bucket, either direct from vessel or picked up from stock. conveyer transfers the coal to a screen house.

COVERED STORAGE, this type may be modified by placing fixed trolley s in the storage building, which match tracks on a traveling unloading , so that one tower may serve several tracks.

versing trolley carrying the bucket may be operated by one of two methods, as "rope" or "man trolley." In the former, the bucket-hoisting and trolley- ing engine or motor is built into the bridge and connected to the bucket and trolley re cables. The operator, from a convenient point, controls the bucket and trolley. ontrolling stations are often installed, one overlooking the boat, for unloading, and her arranged for best supervision of reloading. In the electrically-operated man- . the hoisting and traversing motors are mounted on the trolley, with the control- vers in a cab suspended from it. Usual bucket capacities are 1.5 to 3 tons for the r and 5 to 7.5 tons for the latter. Rope trolley is cheaper in first cost, due to light raction required as compared with man trolley; but is higher in breakage, since the rolley operator is always in view of his work, and can better lower the bucket onto e pile when stocking, thus decreasing the drop and degradation. It also saves by ling and reloading in large units. Fixed bridges may be arranged to span the house, thus eliminating reloading conveyers; but these are limited to small plants equire a bridge and screen house for each size stored.

s type is adapted to stocking separate sizes in varying quantities, with or without eads, as under *K*, but does not lend itself to enlargement. It is usually rapid in ng, the speed depending upon skill of operator; but speed of reloading is limited by reen house capacity. Hoisting speed is about 500 ft per min; trolley speed, up to ft per min. Operating cost is close to 3¢ per ton; degradation, approximately 10%.

17. Ideal Screen House

sential elements. 1. Screens to remove undersize from each size reloaded.
Storage pockets for each size handled, with capacity to hold all the undersize made the size being reloaded, unless sales orders can be so arranged as to permit loading rsize as it is made; otherwise the undersize must be returned to storage when its ing pocket is filled.
Lip screens to remove pocket breakage.
Separate screenings storage floor, with transfer conveyers from screen house to ge, with arrangements to return them to the screens for re-sizing.
Arrangements to load either gondola or box cars.
Minimum breakage.
Minimum force of men, and low operating and first cost.

esign should include a receiving hopper, with feeder to shaker screens, for each size handled, arranged one above the other and directly over the kets. Each size of coal should gravitate directly from its shaker to its et, using telegraphs for reducing breakage. Loading into cars may be as at mines, with preference for belt conveyer system (Art 8). All sizes ve pea should pass over lip screens, the screenings being transferred to nge. Local and interior plants receiving box cars should be equipped with hanical BOX CAR LOADERS.

lting or gravity loader is superior to all others, and has a capacity of 12 box cars per hr. loader, without foundations, costs $10 000; foundations vary from $4 000 in clay, 10 000 in soft water bearing soils requiring piling and a waterproof pit. Less expen- loaders cost from $2 500 to $3 500, but their capacity is less by half than the gravity , and the breakage is higher. COST of a screen plant approximates $10 per ton of ling capacity, not including foundations.

Introduction. Preparation of bituminous c
that of anthracite. Coal is delivered from m
wood, steel or concrete. For the purer coals,
by screens. Impure coal is hand-picked for
say 2.5-in and under.

General considerations. Sizing is by gra
screens. Most tipples are equipped with first
Connellsville, Pa, coke region, and are being
eastern Kentucky. Shaker-screen tipples repl
fines. A tipple may readily be changed from
struction as a whole being no greater than if c

Early in the industry the only preparation
of-mine (r o m) coal, while loading into R R ca
more uniform sizing promotes efficiency. Loa
1.25 in) is practiced at many small mines.

k-back dump. Oldest style is horn dump, Fig 3*a*. It has been im- by addition of springs to assist returning of car after dumping.

lips automatic crossover dump (Fig 3*b*). Standard design is for 2 to ars, 42-in gauge; heavier design built if required. Plate *abcd* is 0.25-in late, or thicker if necessary. Riveted to it are kers. Treadle *A*, generally in right-hand rail, nected to horns *BB'* by chain *C*. Horns are d to shafts *DD'*, set in journal boxes *EE'*. r as shown is empty. A loaded car coming in nto treadle *A*, pressing it forward and down- thereby, through chain *C* and connecting-rods rcing the horns outward. This releases empty hich, on being bumped by loaded car, runs for- ver the crossover rails, while the spring pulls he horns in time to catch next loaded car. The s then released by hand lever *G*, and, being over- d by the weight of coal, tips forward. It is righted by counterweight *H*. ake control is on friction bar *I*. Weight of dump shown, 3 500 lb; capacity, cars per min; price f o b Pittsburg, $250.

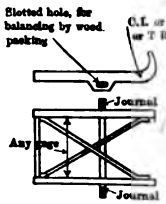

Fig 3*a*. Kick-back Car Dump

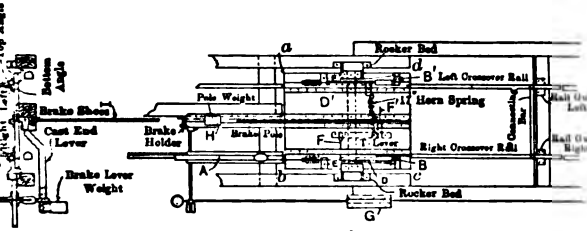

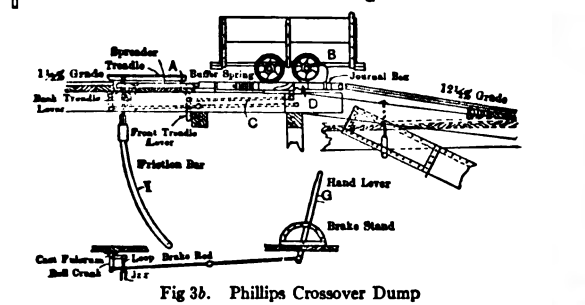

Fig 3*b*. Phillips Crossover Dump

rey crossover dump holds car in dumping position on a steeply inclined ection of rail continuous with tipple track, by a pair of horns which rock ds under control of a band brake on a drum keyed to same shaft; horns unterweighted to bring them back to starting position. Maximum ty, 8 cars (of 3 500 to 5 000 lb) per min; weight of dump, 3 500 lb; price, olumbus, $345. This, and 2 preceding dumps, require end gates on cars.

ary dumps may operate either as crossover or as pull-back; power- ed or automatic. Advantages: no end gates required, and car bodies us be made tight; as many as 18 cars can be dumped at once. Pow

2. Shaker-scr

Shaker screens, built in several design
ing round, square or oblong holes. Thi
gauge. Weight after being perforated is
4 to 5¢ per lb, varying with base price f
of holes.

ish shaker screen (Fig 4) (Wilmot Eng'g Co, Hazelton, Pa) is cheap, light and . The wooden hangers *a* are bolted rigidly to overhead timbers, giving spring-tion to screen, which keeps perforations clear of coal. Driven by eccentrics *c*, flexible wooden rods *b*, bolted rigidly to screen frame and eccentric. Having no s to get loose, the screen runs smoothly and quietly. A 4-deck screen, as in Fig ride by 15 ft long, has capacity of 2 000 tons per 9 hr, making 4 sizes. Weight, c, 4 000 lb; cost (May, 1914) $173, f o b Hazelton.

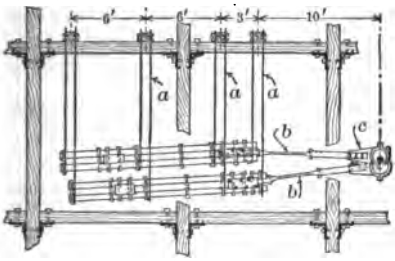

Fig 4. Parrish Shaker Screen

eral design. Fig 5 shows same frame as Fig 1, but with shaker screens ner differences in design. From crossover dump *A*, the coal drops into basket *B*; thence into hopper *C*, kept nearly full to minimize breakage . Below the hopper is a reciprocating feeder *D*, the feed plate of which ated by connecting rod *d*, from driving shaft. About a wheelbarrow of dropped on screen *E* at each stroke of feeder, but this, with number of , may be varied. Screen *E* is 6 by 15.5 ft, with staggered, oblong holes, 2 in (sometimes 2-in round holes). The screen plates are stepped, to more efficiently the nut and slack, which drop into bin *F*. Oversize d lump (sometimes called round, lump and block) go to screen *G*, hav-r 4-in round holes. Egg through *G* drops on picking and loading table ch is a pan conveyer mounted on a movable boom (3). This is pivoted at 5, end elev), so that loading end may be lowered close to bottom of car, reatly reducing breakage. Slate pickers may stand on a platform along-boom (4). Oversize lump from *G* goes to a similar loading boom *I*. boom usually has its own motor *J*, but may be connected with main (20 hp) by belting and clutches.

retarders (3). Three of these, built by Fairmont Mining Mach'y Co, nt, West Va, complete the equipment. They consist of a drum, with rweight and brake. A wire rope from drum passes to the R R car to be the car brakes being slacked. The apparatus is controlled from any bout the tipple, by a small rope led around guide pulleys. Pulling this fts a weighted lever attached to brake. This releases the drum, and al-ar to run by gravity to desired point, where it is spotted by letting the drop, thus braking the drum. The loaded car runs out by gravity, and er rope is detached and rewound on drum by the counterweight. Re-works best with 2% track grades.

mate for shaker-screen, wood-frame tipple, shown by Fig 5 (Jan, Competition in domestic market compels installations almost as com-is this in West Va, eastern Ky, Ill, and Jellico field of Tenn, but they hardly be built in Penn. The estimate assumes a plant within 50 miles bin, Ky.

COAL WA

4. Introdu

Washing is the cheapest and most effi It is usually applied only to 2.5-in sizes picked. For closely associated or combin washing. Since impurities are nearly alw clean coal, washing is in effect concentrati lowing average specific gravities:

	Sp gr		Sp gr
.....	1.00	Slate.....	2.25 to 2.5
.....	1.25 to 1.5	Coal or slate with pyrites..	3.20 to 3.6
al.....	1.45 to 1.8	Pyrites.....	5.00 to 5.2

erard washer, a plunger jig, was introduced in England, 1851; in France, Penn, 1873 (14). It seems probable, however, that coal washing was y practiced. In all washers the coal is agitated with a plentiful f water.

5. Trough and Barrel Washers

h washer (Fig 8), probably the simplest, is a wooden trough *AA*, from ft long, 3 ft wide and 15 in deep. Raw coal enters at hopper *B*, water pipe *C*. Trough has sufficient grade to carry down coal and water, urities settling above the movable dams *D*, while the coal passes over n to screen *E*, where water drains off and washed coal goes to car *F*. is stopped when spaces be- ms are filled with refuse; dams except lowermost are nd refuse is run through to car *H*. The efficiency largely on care in conduct- ation (8).

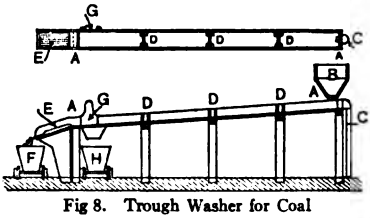

Fig 8. Trough Washer for Coal

washer is an improved trough made by attaching the dams to le chain. This forms a "flight ," which scrapes the refuse to d of trough, discharging into a car, while the coal is washed over the flights to a wer end (10).

kett washer (Fig 9) consists of a revolving barrel, set at an inclination size of coal washed, etc. A shallow worm, attached to inner surface of conveys the heavier "dirt" to upper end, where it is discharged, the coal being washed over the worm and delivered at lower end onto a drainer (15). This washer has probably not been used in U S.

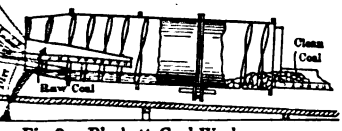

Fig 9. Blackett Coal Washer

Improved Scaife trough washer (9) (Scaife Foundry and Machine Co, Pittsburg, Pa) con- a trough and worm. The worm is a ribbon 0.5 in thick by 2 or 2.5 in onnected by spider arms to a shaft running the entire length, about 24 ft, ni-circular trough, which rocks like a cradle while worm revolves. Trough it pitch of about 1 in 12, depending on material. Coal and water enter at middle point of trough, the coal working over the rim of worm to end, while dirt is delivered by worm at upper end. Average speed, 40 rev m, and 40 double rockings of trough per min. Average capacity, 8 tons al per hr. Water, 3 000 gal per hr, which can be used again after settling. capacity, water, and pitch depend on material to be washed. Approx required, 24 ft long by 2.5 to 6 ft wide by 3 ft deep; approx weight, ; price, f o b Pittsburg, $500.

Net cost of oven				$484.98

rting oven. A wood fire is gradually increased in intensity, adding lump during 2 to 4 days. Sudden heat may crack brickwork. Finally, a small prepared coal is dumped through trunnell head by larry (Fig 26), and front s bricked up, leaving air holes for draft. Product of this charge, called k jack," is discarded or used for starting other ovens. Usually, by fourth h day, a full charge for 48-hr burning may be made, and good coke results.

rge. There is little accurate knowledge of weight of oven charges. ls of coal produce tons of coke, and few superintendents know what a l of coal weighs. Tests in Connellsville field (14) show that average e for 48-hr coke is 5 tons. In S W Virginia, average charge for 48-hr ng seems to be 5.2 to 5.5 tons, for 12.5-ft ovens. General practice today rush coking coal to go through 0.25-in mesh.

eration. After heating oven, about ⅗ of height of door is closed with 6-in brick, and 5 tons of coal charged. To level the charge, a cross bar

17. Machine Drawing (Bee-hive Ovens)

e hard physical labor of pulling coke has stimulated invention of drawing inery. Several successful machines are on the market (25); judging the sales, one of the best is the Covington. For using it, two changes are in the ovens: 1, the doors are wider (42 to 48 in); 2, no wharf (front urm) is necessary, though it is not objectionable.

22 shows design of a block of 50 ovens, at Glamorgan, Va, for machine ing with Covington apparatus. Cost complete, except for machine track some small details, $540 per oven (1910). Fifty ovens built previously $476 each. Higher cost of later block was due to soft ground, requiring er foundations (J. S. Cheyney).

vington coke-drawing machine (Fig 24) has two principal parts, *A* and *A* is a truck, with 4 wheels keyed on axles driven through bevel gears by a p electric motor. *B* is a separate truck, attached to *A* by a draw bar, carrying a horizontal and a boom conveyer, driven by a 15-h p motor. ruck *A* is a steel ram bar *a*, with a rack rail, mounted on a carriage on *A* 23).

e ram is swung in a plane parallel to oven bottom by a 2.5-h p motor. The ram has wings, which close up on entering oven and open on withdrawal by resistance e coke. In operation the duck-bill ram head is forced in under the coke, breaking , and is then pulled back by the 20-h p motor. The opened wings draw out the

coke, which drops into horizontal apron conveyer *c*, composed of overlapping By this, the coke is delivered to conveyer *d*, on track *B*. *d* is of slats, spaced for ing the coke before it reaches the car. Conveyer *c* reaches across face of 2 ovens, o take the last of the charge when cleaned out by hand. The operator sits on left

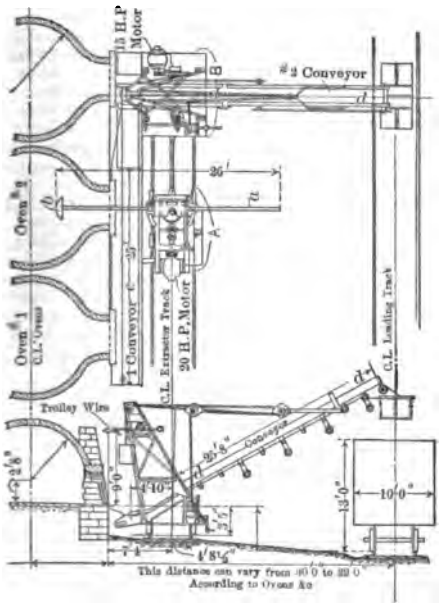

Fig 24. Covington Coke Drawer; General Views

bar, to watch the work in the oven, with controllers at hand. The machine runs odard track (4 ft 8.5 in); total weight, 60 000 to 70 000 lb; avg capacity, 50 ovens -hr day. Power is estimated at 5¢ per oven. Builders, Covington Machine Co, gton, Va; price, f o b works, $5 500 (Feb, 1914).

18. Hand versus Machine Drawing

vantages of machine drawing: 1, lower cost (see below); 2, fewer men, smaller investment in houses; 3, ovens drawn quickly, if enough cars, voiding burning up coke; 4, ovens open for drawing a shorter time, hence ving heat; 5, a charge as deep as can be burned off can be drawn.

advantages of machine drawing: 1, extra cost of oven maintenance , 1.9¢; machine, 7¢ per ton coke); 2, greater breakage of coke, but does not reduce price per ton shipped; 3, tendency of operators to hot coke, thus requiring outside watering; 4, cannot load readily into cars.

st of hand and machine drawing, for 50 ovens, assuming 4.2 tons coke ven; not including delays, which are generally much greater for hand than ine (part of data from catalogue of Covington Machine Works). De- ation on ovens not included.

ALGEBRA

1. Elementary Operations

ıbols of operation are the same in algebra as in arithmetic. The sym- addition is often omitted in arithmetic. Thus, $3\frac{1}{4}$ means $3+\frac{1}{4}$. If a l of operation is omitted in algebra, it is that of multiplication. Thus,

ans $2\times\frac{x}{y}$. $4>x^2$ means that 4 is greater than x^2. $3<ab$ means that s than $a\times b$.

ıbols of aggregation are the bar, | ; vinculum, ——— ; parenthesis, ( ); t, [ ]; and brace, { }. Thus, each of the expressions $\begin{matrix}a\\+c\end{matrix}\Big|$, $\overline{a+c}$,), $[a+c]$, $\{a+c\}$, means that $a+c$ is to be treated as a single number. xpression within a parenthesis is preceded by a plus sign, the parenthesis e removed. If an expression within a parenthesis is preceded by a minus be parenthesis may be removed if the sign of every term within it be d. Thus, $2+(a-b)=2+a-b$; and $2-(a-b)=2-a+b$. If heses occur within parentheses, these may be removed, in succession, by ing first the innermost parenthesis; next, the innermost of all that re- nd so on:

$$\big[6+c-\{d+3\}\big]=a-\big[6+c-d-3\big]=a-\big[3+c-d\big]=a-3-c+d$$

lition. To add like terms, perform the indicated arithmetical operations numerical coefficients; this gives the coeff of the answer. Thus,

$$-7a+6a-2a+a=-2a$$

d terms which are not all like, combine the like terms and write down the , each preceded by its proper sign. Thus,

$$-2ax+4z+5ax-3z-c=3ax+z-c$$

omials are added by adding their respective terms.

s, to add $m^5-3m^4n-6m^3n^2$, $+m^3n^2+m^2n^3-5m^4n$ and $-n^5+2m^5+7m^4n$,

$$\begin{array}{r}
+\ m^5-3m^4n-6m^3n^2\\
\quad -5m^4n+\ m^3n^2+m^2n^3\\
\hline
+2m^5+7m^4n\qquad\qquad -n^5\\
\hline
+3m^5-\ m^4n-5m^3n^2+m^2n^3-n^5
\end{array}$$

btraction. One polynomial may be subtracted from another by changing gn of each term of the subtrahend and adding.

s, $(a^3x^2+2a^2x^3-4ax^4)-(a^5+4a^3x^2-3a^2x^3-4ax^4)=$
$a^3x^2+2a^2x^3-4ax^4-a^5-4a^3x^2+3a^2x^3+4ax^4=-a^5-3a^3x^2+5a^2x^3$

ltiplication. To find the product of monomials, annex the literal factors product of the numerical factors. Thus, $4a\times 2b\times 3z=24abz$. Like produce plus; unlike signs produce minus.

s: $4a\times 3c=+12ac$; $4a\times(-3c)=-12ac$; $-4a\times(-3c)=+12ac$; $a^2\times a^3$ $=aa\times aaa=aaaaa=a^5$; $4a^2c\cdot ac^3=4aac\cdot accc=4aaa\cdot cccc=4a^3c^4$; $6ab^2y^3$ $\times(-5a^2y)=-60a^3b^2y^4$.

multiply two polynomials, multiply each term of one factor by each term other factor and add the partial products.

s, to multiply $(-a^3+2a^2b-b^3)$ by $(+4a^2+8ab)$, the operation may be arranged rried out thus:

$$\begin{array}{r}
-a^3+2a^2b-b^3\\
4a^2+8ab\\
\hline
-4a^5+8a^4b-4a^3b^3\\
\quad -8a^4b\qquad\qquad +16a^3b^2-8ab^4\\
\hline
-4a^5\qquad -4a^4b^3+16a^3b^2-8ab^4
\end{array}$$

STANFORD LIBRARIES

$$\begin{array}{rr} 4\,b^2 & +9 \\ \hline 16\,b^4 & -36\,b^2 \\ & +36\,b^2-81 \\ \hline 16\,b^4 & -81 \end{array}$$

Division is the operation by which, if given, the other factor is determined. The given factor the DIVISOR; and the required is positive if dividend and divisor have and divisor have unlike signs.

$$m^3p^2x^4 + mp^2x^2 = \frac{m^3p^2x^4}{mp^2x^2} = m^2x^2; \qquad -5x$$

To divide a polynomial by a polynomial according to the ascending or descending keep this order throughout the operation.

Dividend $\Big|\,\dfrac{\text{Divisor}}{\text{Quotient}}$. Divide the first term of the divisor and write the result as tiply all terms of the divisor by the first product from the dividend. If there be a dend and proceed as before.

Thus: $(22\,a^4b^2 + 15\,b^4 + 3\,a^4 - 10\,a^3b - 22$

$$\begin{array}{r} 3\,a^4 - 10\,a^3b + 22\,a^2b^2 - 22\,ab^3 \\ \hline 3\,a^4 - 6\,a^3b + 9\,a^2b^2 \\ \hline -4\,a^3b + 13\,a^2b^2 - 22\,ab^3 \\ -4\,a^3b + 8\,a^2b^2 - 12\,ab^3 \\ \hline 5\,a^2b^2 - 10\,ab^3 \\ 5\,a^2b^2 - 10\,ab^3 \end{array}$$

The quotient is $(3\,a^2 - 4\,ab + 5\,b^2)$.

b^4. This type can sometimes be reduced to type 5 by adding multiple of a^2b^2. Thus:

$$x^2 + 4y^4 = (9x^4 + 12x^2y^2 + 4y^4) - 9x^2y^2$$
$$= (3x^2 + 2y^2)^2 - 9x^2y^2$$
$$= (3x^2 + 2y^2 + 3xy)(3x^2 + 2y^2 - 3xy)$$

$(a+b)(a^{n-1} - a^{n-2}b + a^{n-3}b^2 \ldots + b^{n-1})$
$(a-b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 \ldots + b^{n-1})$
} if n is odd.

$^n - b^n$) becomes type 5. In all other cases, if n is a multiple the special types,

$$a^2 + b^2 = (a+b)(a^2 - ab + b^2)$$
$$a^3 - b^3 = (a-b)(a^2 + ab + b^2)$$

$2ab + 2ac + 2bc = (a+b+c)^2$

2. Powers, Roots and Radicals

tween exponential and radical notation is expressed by the $\sqrt[b]{x})^a = x^{\frac{a}{b}}$, in which a and b are any numbers and b is not zero. al exponent, the numerator indicates the power to which the ised and the denominator gives the index of the root which is The fundamental laws of exponents are as follows:

a^n
$= a^{2n}$
$= -a^{2n+1}$
$^{n+n}$
$= a^{m-n}$

6. $a^m b^m = (ab)^m$
7. $a^m \div b^m = (a \div b)^m$
8. $1 \div a^m = (1 \div a)^m = a^{-m}$
9. $a^m = (1 \div a)^{-m} = 1 \div a^{-m}$
10. $(a^m)^n = a^{mn} = (a^n)^m$
11. $a^0 = 1$; $0^2 = 0$; 0^0 = indeterminate

ositive or negative; $\sqrt[2n+1]{+a}$ is positive; $\sqrt[2n+1]{-a}$ is negative.

$\sqrt[2n]{-a}$ is impossible or imaginary and the simplest one is $\sqrt{-1}$, ented by the symbol i. A complex quantity is partly real and y:

$i = \sqrt{-1}$; $i^2 = -1$; $i^3 = -i$; $i^4 = +1$; $\frac{1}{i} = -i$;
$= i^m$; $i^{4n} = +1$; $i^{4n+1} = +i$; $i^{4n+2} = -1$; $i^{4n+3} = -i$.

$\sqrt[n]{a}\sqrt[n]{b}$
$= \sqrt[n]{a} \div \sqrt[n]{b}$

16. $\sqrt[m]{\sqrt[n]{a}} = \sqrt[mn]{a} = a^{\frac{1}{mn}} = \sqrt[n]{\sqrt[m]{a}}$
17. $\sqrt{a} + \sqrt{b} = \sqrt{a+b+2\sqrt{ab}}$

$\frac{1}{\sqrt{a}} = \frac{1}{a^{\frac{1}{m}}} = a^{-\frac{1}{m}}$

g approximations are often convenient and are sufficiently accu- are small compared with 1, and if b is small compared with a:

$1 + 2x$
$= 1 + \frac{x}{2}$
$-x$
$+x$
$+y) = 1 + x + y$

23. $(1+x)(1-y) = 1 + x - y$
24. $(1+x)^2(1-2y)^2 = 1 + 2x - 4y$
25. $\sqrt{ab} = (a+b) \div 2$
26. $\sqrt{a^2 \pm b} = a \pm \frac{b}{2a}$
27. $\sqrt{a^3 \pm b} = a \pm \frac{b}{3a^2}$

$= 0.960a + 0.398b$. This is within 4% of the true value if $a > b$. A ion is $\sqrt{a^2 + b^2} = 0.9938a + 0.0703b + 0.3567\frac{b^2}{a}$.

$+ c^2} = 0.939a + 0.389b + 0.297c$. This is within 6% of the true value or instance, for the numbers 43, 42 and 41, the error $< 5.2\%$.

STANFORD LIBRARIES

8. Binomi

Binomial theorem is used to expa
follows:

$$(a \pm b)^n = a^n \pm na^{(n-1)}b + \frac{n(n-1)}{1 \cdot 2} a^{(}$$

The series is finite if n is a positive
tional or negative; and it is convergent
is called factorial r and may be writte

called binomial coeffs, and the rth coef

The binomial $(a \pm b)^n = a^n (1 \pm x)^n$, in
It is often more convenient to expa
four following special forms can be use
negative or fractional value of n, if x l

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{1 \cdot 2} x^2 \pm \frac{n(n-1}{1 \cdot}$$

$$\frac{1}{1 \pm x} = (1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4$$

$$\sqrt{1 \pm x} = (1 \pm x)^{\frac{1}{2}} = 1 \pm \frac{1}{2}x - \frac{1}{2 \cdot 4} x^2 \pm$$

$$\frac{1}{\sqrt{1 \pm x}} = (1 \pm x)^{-\frac{1}{2}} = 1 \mp \frac{1}{2}x + \frac{1 \cdot 3}{2 \cdot 4} x^2$$

Proportion $a : b :: c : d$ may be writ

Hence, $ad = bc$, $\frac{b}{a} = \frac{d}{c}$, $\frac{a}{c} = \frac{b}{d}$, $\frac{a+b}{b}$

5. Logarithms

Logarithm is the power to which a given fixed number must be raised to uce another number. In $y=b^x$, b is the base, x the logarithm or power, y the number which is produced. For common, or Briggs, logarithms the is 10. The only other system in common use is the Naperian, natural yperbolic system, for which the base is 2.71828. The abbreviation *log* is the logarithm of a number to the base 10. The notation Nap log 6, or 6, means the logarithm of 6 to the base e; and log 6 means the logarithm of the base 10. Thus, log 100 = 2, because $100=10^2$; log 10 = 1, because $10=10^1$; log 1 = 0, because $1=10^0$; log 0.1 = −1, because $0.1=10^{-1}$. Any ber > 1 has a positive logarithm and any number < 1 has a negative ithm. Numbers which are not whole powers of 10 must result from ng 10 to some fractional or irrational power. The decimal part of such ers, or logarithms, may be obtained from a table of logarithms. Since 10 ger than e (2.71828), it takes a higher power of e to produce a given number it does of 10. This means that the logarithm of a number, to base e, is r than to base 10. Relation between the two systems of logarithms is:

$$\log_e n=\log_{10} n+\log_{10} e$$
$$\log_e n=\log_{10} n+0.4343=\log_{10} n\times 2.303$$

6. Choice an

Permutations or choice. If one thing another thing can be done in b different in $a \times b$ different ways. If one thing ca ways, a third in c ways and a fourth in d these things will be $a \times b \times c \times d$. The n elements or things, taken all at a time, is

$$n\,(n-1)\,(n-2)\,(n-3)$$

Probability or chance. If an event ways, each way being equally probable, t happen in a ways is $a \div (a+b)$; the chanc sum of the chances is 1. Odds in favor happening to chance of failure. Odds in

7. Quadratic and C

Linear equations, or those of the first

of the unknown, and have but one root. T

Quadratic equations, or those of the power of the unknown and have two roots. $ax^2 + bx + c = 0$, the roots are $x = \left(-b \pm \sqrt{}\right.$ the roots are real; if $(b^2 - 4\,ac) < 0$, the a perfect square, the roots are rational; i but opposite in sign. Following is an Eu the roots of a quadratic. The equation sh

$$x^2 - 2\,px + q = 0, \text{ or } x$$

Case 1. p and q are both positive factors. On intersecting axes, ox and oy, not necessari unity and $OE = q$, both upwards, and $OF = 2\,p$

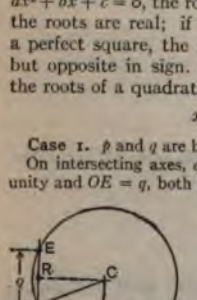

Fig 1

Case 4. p positive and q negative. Lay off $OE = q$ downwards, and proceed as before. On

Case 5. THE CIRCLE DOES NOT CUT OX, there part of the imaginary root can be found by drawin If T is the point of tangency, KT will be the re

Cubic equation, or one of the third deg unknown, may contain the second, first, an which may be imaginary. TRIGONOMETRIC equation is in the form $y^3 + by^2 + cy^2 + d =$ a cubic in which the second power does no

$x - (b + 3)$, expanding and collecting terms; it will then be in the form $px + q = 0$. Three cases must be distinguished:

$x^3 + px + q = 0$
$x^3 - px + q = 0$, and $(p^3 + 27) < (q^2 + 4)$
$x^3 - px + q = 0$, and $(p^3 + 27) > (q^2 + 4)$

} In these, p is necessarily positive and q is positive or negative.

rmulas for Case 1: $\tan A = \frac{2p}{3q}\sqrt{\frac{p}{3}}$, $\tan\frac{1}{2}B = \sqrt[3]{\tan\frac{1}{2}A}$;

roots are, $x_1 = -2\sqrt{\frac{p}{3}}\cot B$, $x_2 = \sqrt{\frac{p}{3}}\cot B + \operatorname{cosec} B\sqrt{p}\sqrt{-1}$, and

$\sqrt{\frac{p}{3}}\cot B - \operatorname{cosec} B\sqrt{p}\sqrt{-1}$

rmulas for Case 2: $\sin A = \frac{2p}{3q}\sqrt{\frac{p}{3}}$, $\tan\frac{1}{2}B = \sqrt[3]{\tan\frac{1}{2}A}$;

roots are, $x_1 = -2\sqrt{\frac{p}{3}}\operatorname{cosec} B$, $x_2 = \sqrt{\frac{p}{3}}\operatorname{cosec} B + \cot B\sqrt{p}\sqrt{-1}$, and

$\sqrt{\frac{p}{3}}\operatorname{cosec} B - \cot B\sqrt{p}\sqrt{-1}$

rmula for Case 3: $\sin A = \frac{3q}{2p}\sqrt{\frac{3}{p}}$;

oots are, $x_1 = 2\sqrt{\frac{p}{3}}\sin\frac{A}{3}$, $x_2 = 2\sqrt{\frac{p}{3}}\sin\left(60° - \frac{A}{3}\right)$

$x_3 = -2\sqrt{\frac{p}{3}}\sin\left(60° + \frac{A}{3}\right)$

8. Interest

mple interest. Let principal $= P$, yearly rate $= r\%$, amount of \$1 for ar $= R$, number of years $= n$ and amount of P for n years $= A$; then $1 + r$, the interest on P for n years $= Prn$, and $A = P(1 + nr)$. P is some- called the present worth of A. If d = any number of days, simple interest hat time is given by following formulas: At 4%, interest $= Pd \div 9\,000$; $Pd \div 7\,200$; 6%, $Pd \div 6\,000$; 8%, $Pd \div 4\,500$.

6% is a very common rate, it is worth recalling that interest for 1 month $\times 6) \div (12 \times 100) = P \div 200$; divide this by 30 to get the interest for 1 and multiply the last result by d to get the interest for d days. Proportional parts of these results may be taken for other percentages.

mple. The interest on \$5 284 for 30 days at 6% $= 5\,284 \div 200 =$ \$26.42; interest for 1 day $= 26.42 \div 30 =$ \$0.8807; interest for 12 days $= 12 \times 0.8807 =$ \$10.568. e 6% formula given above the interest for 12 days would be $(\$5\,284 \times 12) \div 6\,000 =$ 68. At 4%, the interest for the 12 days would be ⅔ \$10.57 = \$7.04. At 7%, the at would be \$10.57 + ⅙ 10.57 = \$12.33.

mpound interest. If, at the end of a period, interest is added to the ipal, then interest charged on the new principal, the second period's in- added to form a new principal and so on, the interest is said to be com- ded. With notation as before, $A = PR^n$, or $P = A \div R^n$.

mple. In 12 years at 6%, \$400 amounts to $A = 400\,(1.06)^{12} =$ \$804.88.

ent worth of \$5 000 due in 15 yr at 5% comp'd interest is $P = \frac{5\,000}{(1.05)^{15}} =$ \$2 405.09.

nterest is to be added to principal g times each year, $A = P\left(1 + \frac{r}{g}\right)^{gn}$

Example. The amount of $400 in 12 y
quarterly will be $A = 400\left(1 + \frac{0.06}{4}\right)^{4\times 12} =$
yearly, and instead of $688.00 by simple inte

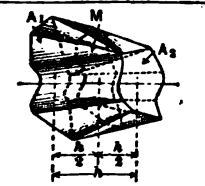
$$V = \frac{\pi}{8} \times b^2 \times h$$



56. Prismatoid [Irregular with bases in parallel planes]

If the planes connecting the bases are curved or warped they may be replaced by flat surfaces, best suited to the contour, formed by straight lines from one of the two parallel bases to the other. These planes may be parallelograms, triangles, or trapezoids.

Let A_1 = the area of one of the bases.

A_2 = the area of the other base.

M = the area of the cross-section parallel to, and midway between, the two bases.

h = the altitude of the prismatoid. (The perpendicular distance between the two parallel bases).

V = the volume of the solid.

smoidal Formula..... $V = \frac{1}{6} h [A_1 + 4M + A_2]$

[The area of the cross-section M should be computed from the dimensions of the polygon formed by the intersection, with the solid, of a plane parallel to the bases through the middle point of the altitude. In only exceptional cases is this cross-section the average of the two areas. However, the perimeter of this mid-polygon is half the sum of the basal perimeters]

Example. Find the volume of the irregular solid shown in Fig 57. *AEFGD* is the lower base; *HLMOP* is the upper base.

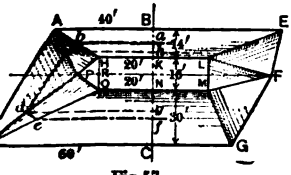


Fig 57

To simplify the problem, let the perpendicular plane *BKNC* divide the solid into two parts; find the volumes of the parts separately and sum them for total volume.

For the left portion of the solid: *ABCD* is the trapezoidal lower base, *HKNOP*, the pentagonal upper base. The given data is as follows:

Altitude, or perpendicular distance between bases = 50 ft

$AB = 40$ ft $\quad BK = 14$ ft $\quad KN = 16$ ft $\quad BC = 60$ ft

$HK = ON = 20$ ft $\quad DC = 60$ ft $\quad NC = 30$ ft $\quad HR = RO = PR = 8$ ft

imensions necessary to calculate area of cross-section M are:

40 ft, $dg = 44$ ft, $ch = 34$ ft, $ba = 30$ ft, $fg = 4$ ft, $gh = 30$ ft, $ha = 4$ ft

heck: Perimeter of lower base = 223.24 ft; perimeter of upper base = 78.62 ft; meter of mid-polygon = 150.93 ft;

$$\text{half sum of basal perimeters} = \frac{223.24 + 78.62}{2} = 150.93 \text{ ft}$$

$ABCD = A_1 = 3\,000$ sq ft; area $HKNOP = A_2 = 384$ sq ft; area $afedcb = M$ 466 sq ft; hence $V_{left} = \frac{50}{6}[3\,000 + 4(1\,466) + 384] = \frac{50}{6}[9\,248] = 77\,067$ cu ft.

he volume to the right of plane *BKNC* may be found in a similar manner.

Polar equation. Origin on circumfere line, equation of circle is $\rho = a\cos\theta$. Dia (Fig 66) is $\rho = a\sin\theta$.

18. Ellipse

ation of ellipse with center at origin and foci F' and F on the x-axis $\overline{F'F}$), is

$$(x^2 + a^2) + (y^2 + b^2) = 1 \qquad (E)$$

a is the major semiaxis and b the minor semiaxis.

tance $OF = \sqrt{a^2 - b^2}$; distance $BF = OA =$ al width $QR = 2b^2 + a$.

centricity e of ellipse is $e = \sqrt{a^2 - b^2} + a =$ OA, and e is always less than 1. When e is o, the ellipse is nearly a circle, and the re near the center. When e is nearly 1, is long and narrow, and foci are near ends major axis. If two ellipses have the same ricity, the ratio of semiaxes, $a : b$, is the for both, and conversely. The equation

$$(x^2 + a^2) + (y^2 + b^2) = k$$

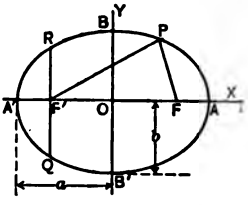

Fig 67

a and b are fixed, represents, whenever any positive value is assigned to ellipse; and all these ellipses have the same e.

ocal ellipses. If two ellipses $(x^2 + a^2) + (y^2 + b^2) = 1$ and $(x^2 + a'^2) + (y' + b^2)$ e the same foci, then $a^2 - b^2 = a'^2 - b'^2$. In other words, $a^2 - a'^2 = b^2 - b'^2$.

l radii to the point $P(x', y')$ on the ellipse are $F'P = a + ex'$ and $FP = a - ex'$. akes $F'P + FP = 2a = A'A$.

gents to the ellipse (E) at (x', y') on the curve $(x'x + a^2) + (y'y + b^2) = 1$; with $y = mx \pm \sqrt{a^2m^2 + b^2}$.

neters (Fig 68). Equation of diameter AB, which bisects all chords having as CD, EF, in ellipse (E) is $y = (-b^2 + a^2m)\,x$. If the slopes m and m' of two ers of (E) are such that $mm' = -b^2 + a^2$, each diam bisects all chords parallel other. They are called conjugate diameters; for example, AB and JK.

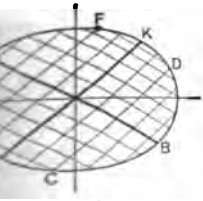

Fig 68

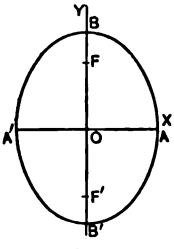

Fig 69

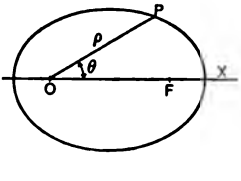

Fig 70

on y-axis (Fig 69). If the foci of an ellipse are on the y-axis, its equation is (E) . but b is the major semiaxis, a the minor, so that $OF = \sqrt{b^2 - a^2}$, $AF = b$, and $\sqrt{b^2 - a^2} + b$.

equation (Fig 70). Initial line along major axis of ellipse, origin at left-hand $\rho = b^2 + a(1 - e\cos\theta)$. With origin at right-hand focus, $\rho = b^2 + a(1 + e\cos\theta)$. **igin at center,** $\rho^2 = b^2 + (1 - e^2\cos^2\theta)$, where e is the eccentricity.

Change of axes changes the equation of a origin is moved to the point (h, k), axes rema $x + h$ for x, and $y + k$ for y. If axes are rotat substitute $x\cos\theta - y\sin\theta$ for x, and $x\sin\theta +$

22. Solid G

Distance from $P_1(x_1, y_1, z_1)$ to $P_2(x_2,$

$$d = \sqrt{(x_2 - x_1)^2 + (y$$

, $P_1Q = x_2 - x_1$, $QR = y_2 - y_1$, $RP_2 = z_2 - z_1$, these segments being parallel
ie axes (Fig 83).

irection cosines of P_1P_2 are

$$= \frac{x_2 - x_1}{d}, \quad \cos\beta = \frac{y_2 - y_1}{d}, \quad \cos\gamma = \frac{z_2 - z_1}{d},$$

e d is the distance from P_1 to P_2, given
e. The sum of the squares of direction
es is always 1, $\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$.
e direction cosines of a line are propor-
l to a, b, c, they are $\cos\alpha = a \div k$, $\cos\beta =$
, $\cos\gamma = c \div k$, where $k = \sqrt{a^2 + b^2 + c^2}$.

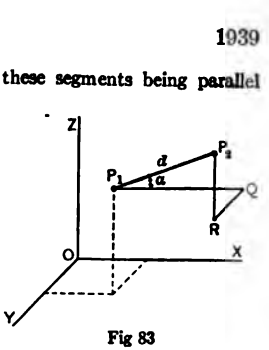

Fig 83

ıne. Every equation of first degree in x, y, and z, as

$$Ax + By + Cz = D \qquad (P)$$

ents a plane. Its intercepts on the x-, y- and z-axes are $D \div A$, $D \div B$,
. If the plane goes through the origin, $D = 0$. The direction cosines of
perpendicular to the plane are $\cos\alpha = A \div q$, $\cos\beta = B \div q$, $\cos\gamma = C \div q$,
$q = \sqrt{A^2 + B^2 + C^2}$.

stance from point (x', y', z') **to plane** (P) is

$$r = (Ax' + By' + Cz' - D) \div q$$

nce from origin to plane is $p = D \div q$.

gle θ **between two planes,** $Ax + By + Cz = D$ and $A'x + B'y + C'z = D'$,
n by $\cos\theta = (AA' + BB' + CC') \div \sqrt{A^2 + B^2 + C^2} \cdot \sqrt{A'^2 + B'^2 + C'^2}$,

$$\cos\theta = \cos\alpha\cos\alpha' + \cos\beta\cos\beta' + \cos\gamma\cos\gamma'$$

$\cos\alpha$, $\cos\beta$, $\cos\gamma$ are direction cosines of a perpendicular to one plane,
s α', $\cos\beta'$, $\cos\gamma'$ are direction cosines of a perpendicular to the other.
E BETWEEN TWO LINES, the direction cosines of which are known, is given
: second of the foregoing formulas.

pendicular lines or planes. Two lines are perpendicular if

$$\cos\alpha\cos\alpha' + \cos\beta\cos\beta' + \cos\gamma\cos\gamma' = 0$$

same condition holds for planes. More simply, the two planes

$$Ax + By + Cz = D \quad \text{and} \quad A'x + B'y + C'z = D'$$

rpendicular if $AA' + BB' + CC' = 0$.

e of intersection of two planes, $Ax + By + Cz = D$ and $A'x + B'y + C'z$
has the direction cosines: $\cos\alpha = a \div s$, $\cos\beta = b \div s$, $\cos\gamma = c \div s$, where
$= BC' - B'C$, $b = AC' - A'C$, $c = AB' - A'B$, and $s = \sqrt{a^2 + b^2 + c^2}$

ıations of straight line through two points (x_1, y_1, z_1) and (x_2, y_2, z_2):

$$(x - x_1) \div (x_2 - x_1) = (y - y_1) \div (y_2 - y_1) = (z - z_1) \div (z_2 - z_1)$$

ions of line through (x_1, y_1, z_1), with direction cosines $\cos\alpha$, $\cos\beta$, $\cos\gamma$:

$$(x - x_1) \div \cos\alpha = (y - y_1) \div \cos\beta = (z - z_1) \div \cos\gamma$$

ne through three points, P (x_1, y_1, z_1), Q (x_2, y_2, z_2), R (x_3, y_3, z_3). The
on of the plane may be taken as $ax + by + cz = 1$, by dividing (P) above by
ess $D = 0$. Substitute in this equation, for x, y, and z, the coordinates of
n those of Q and finaliy those of R. This gives three equations, from

which the unknowns a, b, and c can be found. This process fails if the pl through P, Q, R goes through the origin, in which case, the equation is

$$Ax + By + Cz = 0$$

and may be divided by A, becoming $x + by + cz = 0$.

Sphere. Equation of sphere, with center (a, b, c) and radius r, is

$$(x-a)^2 + (y-b)^2 + (z-c)^2 = r^2$$

Cylinder. Equation of circular cylinder, with axis on z-axis and radi is $x^2 + y^2 = r^2$. Every equation containing only two of the variables x, represents in solid geometry a cylinder, the base of which is the curve d mined in one of the coordinate planes by the given equation.

Surface of revolution. If any curve $y = f(x)$ rotates about the x- the equation of the surface generated is $y^2 + z^2 = [f(x)]^2$. Thus, if the el $(x^2 \div a^2) + (y^2 \div b^2) = 1$ (that is, $y = (b \div a)\sqrt{a^2 - x^2}$) rotates about the x- the equation of the resulting ellipsoid of revolution is $y^2 + z^2 = (b^2 \div a^2)(a^2 -$ or $(x^2 + a^2) + (y^2 \div b^2) + (z^2 \div c^2) = 1$.

Intercepts. The x-intercept of any surface is found by setting $y = 0$ $z = 0$ in the equation of the surface; similarly for y and z intercepts.

Traces. The trace of any surface on the xy-plane is the curve found putting $z = 0$ in the equation of the surface; similarly for the xz-trace and trace. Thus, the xy-trace of the plane $2x - y + 3z = 11$ is the line $2x - y =$ The yz-trace is $-y + 3z = 11$.

Cross-section of surface. The equation of the cross-section of any face the equation of which is known, taken parallel to the xy-plane at the tance k from the xy-plane, is found by putting $z = k$ in the equation of surface. For cross-section parallel to yz, put $x = k$. For cross-sec parall xz, put $y = k$. Thus, cross-sec of sphere $x^2 + y^2 + z^2 = 36$, parallel to xy a tance $z = 2$, is $x^2 + y^2 + 4 = 36$, or $x^2 + y^2 = 32$. It is a circle with radius $\sqrt{}$

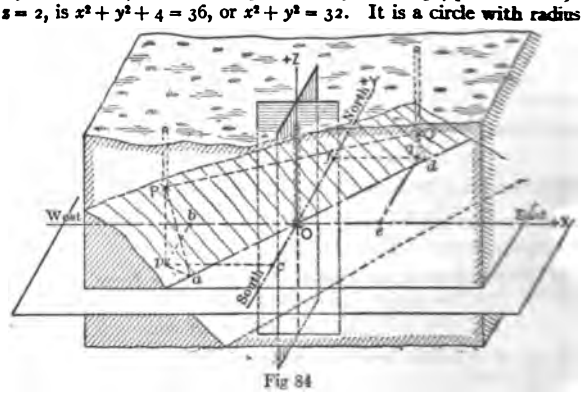

Fig 84

Dip and strike of stratum. (See also Sec 10.) Suppose three points of a str (Fig 84), which is approx a true plane, are determined as follows:

Point	Latitude	Departure	Elev	x	y	z
O.....	−312.5	305.4	517.4	0	0	0
P.....	−624.2	124.6	759.7	−311.7	−180.8	24: 1
Q.....	− 48.0	558.7	621.4	264.5	−353.3	104

e a horiz plane through the lowest point O as xy-plane, and the vertical through O is (elev). Then the coordinates of O, P, and Q are as above. Let the equation of atum plane be $x + by + cz = 0$. (See Equation of Plane Through Three Points) Substituting the coordinates of P, and then of Q, for x, y and z,

$$-311.7 - 180.8\,b + 242.3\,c = 0, \text{ and } 264.5 + 253.3\,b + 104\,c = 0;$$

$;6\,b + c = +1.286$, and $2.435\,b + c = -2.543$. Hence $b = -2.267$, $c = 2.977$, e equation of the stratum plane is

$$x - 2.267\,y + 2.977\,z = 0 \qquad (S)$$

on of xy or horiz plane is $z = 0$, or

$$0x + 0y + z = 0 \qquad (H)$$

is angle between (H) and (S) (see Angle between Two Planes),

$$\cos\theta = \frac{1 \times 0 - 2.267 \times 0 + 2.977 \times 1}{\sqrt{1^2 + (-2.267)^2 + 2.977^2} \times \sqrt{0^2 + 0^2 + 1^2}} = 0.769$$

$\theta = 39° 40'$ approx = dip.

ind the strike, find the intersection of stratum plane (S) with horiz plane (H). s, put $z = 0$ in (S). This gives the horiz line

$$x - 2.267\,y = 0, \text{ or } y = 0.441\,x \qquad (L)$$

ope of this line, $\tan\alpha$, is the tangent of the complement of the strike angle. But = 0.441. Hence, $\alpha = 23° 50'$, $\beta = 90° - \alpha = 66° 10'$, and strike = N 66° 10′ E.

CALCULUS

23. Derivative

$f(x)$ be any function of x, and denote it by y; then $y = f(x)$. When x es by any amount, Δx, then y changes by some amount, Δy. The de-

ve of the function with respect to x, denoted by $\frac{dy}{dx}$ or $f'(x)$, is

$$\lim_{\Delta x \doteq 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \doteq 0} \frac{f(x+\Delta x) - f(x)}{\Delta x} = \frac{dy}{dx} = f'(x)$$

a table of derivatives see Art 25. (Symbol $\doteq$ means "approaching.")

pe. Value of the derivative for a particular value of x, $x = x_1$, is the of the curve $y = f(x)$ at the point (x_1, y_1).

gent and normal. Equation of the tangent to any curve $y = f(x)$ at oint (x_1, y_1) is $y - y_1 = f'(x_1)(x - x_1)$, where $f'(x_1)$ denotes the value of when $x = x_1$.

ation of normal at (x_1, y_1) is $y - y_1 = (-1 + f'(x_1))(x - x_1)$.

xima and minima. To find maximum or minimum of a given function set $f'(x) = 0$ and find its roots, say $x = x_1$, $x = x_2$, . . . Then $f(x)$ has a

maximum for $x = x_1$ if $f''(x_1)$ is negative,
minimum for $x = x_1$ if $f''(x_1)$ is positive,

$f''(x_1)$ means the result of substituting x_1 for x in $f''(x)$, the second tive of $f(x)$ with respect to x.

owever, $f'(x_1) = 0$, compute $f'''(x_1)$, $f''''(x_1)$ and further derivatives, until one n, say the kth, is found which is not zero when $x = x_1$. Then $f(x)$ has a maximum $= x_1$ if k is even and $f^k(x_1)$ is negative, a minimum if k is even and $f^k(x_1)$ is posi- ut a point of inflexion on a horizontal tangent if k is odd.

at of inflexion. To find points of inflexion of the curve $y = f(x)$, find ots of $f''(x) = 0$. Any such root x_1 gives a point of inflexion, unless $) = 0$ also. For this exceptional case, see preceding note.

Curvature. Curvature k of curve $y = f(x)$, at any point (x, y), is

$$k = f''(x) \div \sqrt{(1 + [f'(x)]^2)^3}$$

Radius R of curvature is the reciprocal of curvature, $R = 1 \div k$.
Center (a, b) of curvature,

$$a = x - f'(x)\,(1 + [f'(x)]^2) \div f''(x)$$
$$b = y + (1 + [f'(x)]^2) \div f''(x)$$

Angle from radius vector to tangent, in polar coordinates. If the tion of the curve is $\rho = f(\theta)$, the angle ϕ from radius vector to tangent is by $\tan \phi = \rho\,(d\theta \div d\ )$.

Taylor's theorem.

$f(x) = f(a) + f'(a)(x-a) + [f''(a)\,(x-a)^2 \div 2!] + [f'''(a)(x-a)^3 \div 3!] +$ ·

where $3!$ denotes $3 \cdot 2 \cdot 1$. If $a = 0$, the theorem is

$$f(x) = f(0) + f''(0)\,x + [f''(0)\,x^2 \div 2!] + [f'''(0) \div 3!] + \cdots$$

Usually this series is more and more nearly equal to $f(x)$ when more and terms are taken, but there are many exceptions.

Derivative of arc. If s denotes length of arc of a curve $y = f(x)$, s va as the point (x, y) moves along the curve, then $\dfrac{ds}{dx} = \sqrt{1 + \left(\dfrac{dy}{dx}\right)^2}$

Function of a function. If y is a function of u and u is a function $\dfrac{dy}{dx}$ may be found by $\dfrac{dy}{dx} = \dfrac{dy}{du} \times \dfrac{du}{dx}$.

24. Integration

Integral. The integral of $f(x)$, denoted by $\int f(x)\,dx$, means the fun the derivative of which is $f(x)$. For example, $\int 3x^2\,dx = x^3 + C$, C being constant.

For a table of integrals of a few functions, see Art 26.

Definite integral. The symbol $\int_a^b f(x)\,dx$ denotes the result of fin $\int f(x)\,dx$, substituting in the resulting function b for x, then a for x and tracting, thus: $\int_a^b f(x)\,dx = \phi(b) - \phi(a)$, where $\phi(x) = \int f(x)\,dx$

The definite integral gives the value of the limit of the sum of term structed as follows: Divide the interval from a to b into n equal parts denote the abscissas x of the points of division by $x_0, x_1, x_2, \ldots x_{n-1}, x_n$ be and x_n being b. Let each part of the interval thus divided be Δx. Then

$$\int_a^b f(x)\,dx = \lim_{n \doteq \infty} [f(x_1)\,\Delta x + f(x_2)\,\Delta x + \cdots + f(x_n)\,\Delta x]$$

Area. In rectangular coordinates, the area under the curve $y = f$ cluded between ordinates, at $x = a$ and $x = b$ is $A = \int_a^b f(x)\,dx$. If the c crosses the x-axis between a and b, compute area to crossing, and then beyo In polar coordinates, area between the curve $\rho = f(\theta)$ and two radii at θ

$= \theta_2$ is given by $A = \frac{1}{2}\int_{\theta_1}^{\theta_2} \rho^2\, d\theta$. For double integration the element of
A is $dA = dy\,dx$, or $dA = \rho\, d\rho\, d\theta$.

gth of arc of curve $y = f(x)$ from $P_1(x_1, y_1)$ to $P_2(x_2, y_2)$:

$$s = \int_{x_1}^{x_2} \sqrt{1 + m^2}\, dx, \qquad \text{where } m = f'(x)$$

$$s = \int_{\theta_1}^{\theta_2} \sqrt{\rho^2 + k^2}\, d\theta, \qquad \text{where } k = \frac{d\rho}{d\theta}$$

ume and surface of revolution. If the curve $y = f(x)$ revolves about the volume generated by area under the curve and between ordinates x_1 and $x = x_2$, is $V = \pi \int_{x_1}^{x_2} y^2\, dx$, and surface generated by arc of curve is

$$S = 2\pi \int_{x_1}^{x_2} x\sqrt{1 + m^2}\, dx, \qquad \text{where } m = f'(x)$$

ter pressure. Pressure on vertical area bounded by the curve $y = f(x)$ wo horizontal lines at $y = y_1$ and $y = y_2$ is $P = k \int_{y_1}^{y_2} hw\, dy$, where k is pth below water surface of a narrow horiz strip at distance y from origin, e width of this strip, and ight per unit volume. h nust be expressed in terms fore proceeding with the tion.

nent of volume, multi-tegration. Element of under surface the equa- which is $z = f(x, y)$:

$dV = dz\,dx\,dy$, for triple integration
} rectangular coordinates.
$dV = \rho\, d\rho\, d\theta\, dz$, cylindrical coordinates,
$dV = \rho^2 \sin\phi\, d\phi\, d\theta\, d\rho$, spherical coordinates.

25. Table of Derivatives

is table u and v denote functions of x; a, c, and n are arbitrary constants.

$c = 0$

$(uv) = u\frac{dv}{dx} + v\frac{du}{dx}$

$\left(\frac{u}{v}\right) = \left(v\frac{du}{dx} - u\frac{dv}{dx}\right) \div v^2$

$u^n = nu^{n-1}\frac{du}{dx}$

$e^u = e^u\frac{du}{dx}$ (where $e = 2.718+$)

$a^u = a^u \log_e a \cdot \frac{du}{dx}$

$u^v = vu^{v-1} + u^v \log_e u\frac{dv}{dx}$

$\frac{d}{dx}\log_e u = \frac{1}{u}\frac{du}{dx}$

$\frac{d}{dx}\log_{10} u = \frac{\log_{10} e}{u} \cdot \frac{du}{dx}$

$\frac{d}{dx}\sin u = \cos u\frac{du}{dx}$ (u in radians)

$\frac{d}{dx}\cos u = -\sin u\frac{du}{dx}$

$\frac{d}{dx}\tan u = \sec^2 u\frac{du}{dx}$

$\frac{d}{dx}\cot u = -\csc^2 u\frac{du}{dx}$

$\frac{d}{dx}\sec u = \sec u \tan u\frac{du}{dx}$

$$\frac{d}{dx}\csc u = -\csc u \cot u \frac{du}{dx}$$

$$\frac{d}{dx}\sin^{-1} u = \frac{1}{\sqrt{1-u^2}}\frac{du}{dx}$$

$$\frac{d}{dx}\cos^{-1} u = -\frac{1}{\sqrt{1-u^2}}\frac{du}{dx}$$

$$\frac{d}{dx}\tan^{-1} u = \frac{1}{1+u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\cot^{-1} u = -\frac{1}{1+u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\sec^{-1} u = \frac{1}{u\sqrt{u^2-1}}\frac{du}{dx}$$

$$\frac{d}{dx}\csc^{-1} u = -\frac{1}{u\sqrt{u^2-1}}\frac{du}{dx}$$

26. Table of Integrals

The base e is assumed for logarithms unless otherwise noted. A constant is understood to be added to each result.

$$\int dx = x + C$$

$$\int x^n dx = \frac{x^{n+1}}{n+1}, \quad \text{except when } n = -1$$

$$\int x^{-1} dx = \int \frac{dx}{x} = \log x$$

$$\int \frac{dx}{ax+b} = \frac{1}{a}\log(ax+b)$$

$$\int (ax+b)^n dx = \frac{(ax+b)^{n+1}}{a(n+1)}, \quad \text{except when } n = -1$$

$$\int \frac{dx}{ax^2+b} = \frac{1}{\sqrt{ab}}\tan^{-1}\sqrt{\frac{a}{b}}\,x, \quad \text{when } a > 0 \text{ and } b > 0$$

$$\int \frac{dx}{ax^2-b} = \frac{1}{2\sqrt{ab}}\log\frac{\sqrt{a}\,x-\sqrt{b}}{\sqrt{a}\,x+\sqrt{b}}, \quad \text{when } a > 0 \text{ and } b > 0$$

$$\int \sqrt{x^2+a^2}\,dx = \tfrac{1}{2}\left[x\sqrt{x^2+a^2} + a^2\log\left(x+\sqrt{x^2+a^2}\right)\right]$$

$$\int \sqrt{x^2-a^2}\,dx = \text{same as above, with } -a^2 \text{ for } a^2$$

$$\int \sqrt{a^2-x^2}\,dx = \tfrac{1}{2}\left(x\sqrt{a^2-x^2} + a^2\sin^{-1}\frac{x}{a}\right)$$

$$\int \frac{dx}{\sqrt{a^2-x^2}} = \sin^{-1}\frac{x}{a}$$

$$\int \log x\,dx = x(\log x - 1)$$

$$\int \log_{10} x\,dx = x\log_{10}\frac{x}{10}$$

$$\int e^{ax}dx = \frac{e^{ax}}{a}$$

$$\int a^x dx = \frac{a^x}{\log a}$$

$$\int xe^x dx = e^x(x-1)$$

$$\int \sin x\,dx = -\cos x$$

$$\int \cos x\,dx = \sin x$$

$$\int \sin^2 x\,dx = \frac{x}{2} - \frac{\sin 2x}{4}$$

$$\int \cos^2 x\,dx = \frac{x}{2} + \frac{\sin 2x}{4}$$

$$\int \tan x\,dx = -\log\cos x$$

$$\int \cot x\,dx = \log\sin x$$

$$\int \sec x\,dx = \log(\sec x + \tan x)$$

$$\int \sec^2 x\,dx = \tan x$$

$$\int \csc x\,dx = \log(\sec x - \tan x)$$

$$\int \csc^2 x\,dx = \cot x$$

$$\int x\sin x\,dx = \sin x - x\cos x$$

$$\int x^2\sin x\,dx = 2x\sin x + (2 - x^2)\cos x$$

$$\int x\cos x\,dx = \cos x + x\sin x$$

$$\int x^2\cos x\,dx = 2x\cos x + (x^2 - 2)\sin x$$

STATICS

27. Definitions

:hanics is that branch of science which treats of forces and motion. s deals with the action of forces on bodies at rest. DYNAMICS deals ie action of forces on bodies in motion.

ce is that which changes or tends to change the state of rest or motion ody. A force is completely specified by its magnitude, direction and f application. The word SENSE as applied to a force refers to one of the rections along the line of action of the force. The effect of any force l to a rigid body at rest is the same, no matter where in its own line of the force is applied. This is known as the principle of the TRANSMISSI-OF FORCE. A force may be represented graphi- magnitude and direction by a straight line parallel to its line of action, the length being ional to the magnitude of the force; its sense is ed by an arrowhead placed on the line. The engineers' UNIT OF FORCE is the pound, or the pull on a mass of 1 lb. A drawing which indi- he lines of action of the various forces acting on ine or structure is called a SPACE DIAGRAM; the which vectors are drawn to represent the magni- nd directions of the forces is a VECTOR DIAGRAM. A force is indicated on diagram by two lower-case letters placed on opposite sides of the line of of the force; the vector, representing its magnitude and direction, by ne capital letters placed at the ends. Thus, in Fig 87, AB represents gnitude and direction of the force W, and ab its action line. The vector ead as AB indicates a downward sense; read as BA, an upward sense. es are classified according to the arrangement of their action lines:

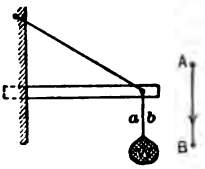

Fig 87

planar: *a*. concurrent; *b*. nonconcurrent; *c*. parallel
oncoplanar: *a*. concurrent; *b*. nonconcurrent; *c*. parallel

number of forces taken collectively is a system or set of forces. A is coplanar or noncoplanar according as the lines of action of the forces o not lie in the same plane, and is concurrent or nonconcurrent according do or do not intersect in a point. Two or more forces which are the ent of a single force are COMPONENTS of the force. The operation of g a system of forces by a simpler system is called COMPOSITION of forces. TION of forces is the operation of replacing a single force by a system es. RESULTANT of a force system is the simplest equivalent system. e cases the simplest equivalent is a single force; in other cases, it is a couple; in still others it is a pair of forces which are not parallel and do not intersect (noncoplanar).

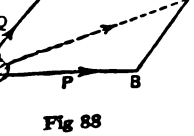

Fig 88

28. Resultants of Concurrent Forces

Resultant of two concurrent forces. PARALLELOGRAM LAW. If two concurrent forces P and Q (Fig 88), acting at the point O of a re represented in magnitude and direction by the adjacent sides OB and parallelogram $OACB$, their resultant is represented by diagonal OC through point of concurrency O. TRIANGLE LAW. If in the triangle

ABC (Fig 89) AB and BC represent two concurrent forces in magni direction and sense, then AC will represent their resultant in magni direction and sense; its action line will be ac, through the point currency, parallel to AC. The resultant may be found algebraically In Fig 90, let α be the angle between the action lines of forces P and Q,

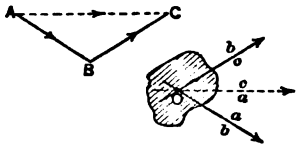

Fig 89

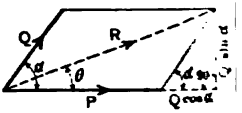

Fig 90

the angle between R and P. Then, $R^2 = P^2 + Q^2 + 2PQ \cos\alpha$, and $\tan\theta = \frac{Q \sin\alpha}{P + Q\cos\alpha}$. If $\alpha = 90°$, $R^2 = P^2 + Q^2$, and $\tan\theta = Q \div P$.

A force may be resolved into an infinite number of pairs of compone constructing different triangles as in Fig 91. The action lines of the c

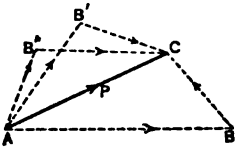

Fig 91

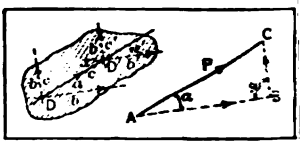

Fig 92

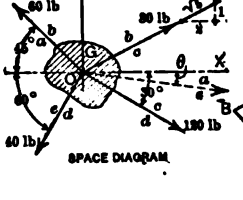
nents must be concurrent at a point on the action line of the force. A con problem is to resolve a force into rectangular components (often called re parts). In Fig 92, AB and BC are the rectangular components of the fo Expressed algebraically, $AB = P\cos\alpha$ and $BC = P\sin\alpha$. In general, th solved part of a force along any line equals the magnitude of the force time cosine of the angle between the lines of action of the force and its comp Action lines of the components are concurrent on the space diagram a point on ac, as at D or D'.



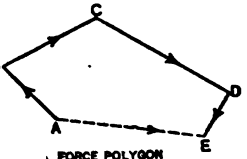


Fig 93

Resultant of coplanar concurrent forc found graphically as follows: In Fig 93, body G acted the 4 forces Construct a fo gon. Plat AB pa to ab, and scale represent 60 l. B plat BC par bc, and scale it resent 80 lb; manner plat DE, so that the arrows lead confluently from A to E. The resultant system is AE in magnitude and sense = 114 lb, and its action line is ac, an angle of $\theta = \tan^{-1} 0.146 = 8°\ 20'$ with the horizontal. ALGEBRAIC SO Choose rectangular axes OX and OY. Resolve each force into its x

ents, considering components acting upward or to the right as positive, ose acting downward or to the left as negative. Arrange the results in : form, placing the forces in the first column, the x components in the and the y components in the third. ΣF_x = algebraic sum of x com-s, and ΣF_y = algebraic sum of y components.

F, lb	F_x, lb	F_y, lb
= 60	$-60 \times 0.707 = -42.4$	$+60 \times 0.707 = +42.4$
= 80	$+80 \times 2/\sqrt{5} = +71.4$	$+80 \times 1/\sqrt{5} = +35.7$
= 120	$+120 \times 0.866 = +104$	$-120 \times 0.5 = -60$
= 40	$-40 \times 0.5 = -20$	$-40 \times 0.866 = -34.6$
	$\Sigma F_x = +113$	$\Sigma F_y = -16.5$

$R = \sqrt{\Sigma F_x^2 + \Sigma F_y^2} = \sqrt{13\,041} = 114$ lb. Sense is downward and to right (Fig 94). *Tan* $\theta = \dfrac{\Sigma F_y}{\Sigma F_x} =$ $\theta = 8° 20'$. If a concurrent system esultant, it is a single force.

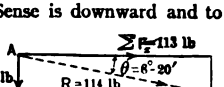

Fig 94

ultant of noncoplanar concurrent

Parallelopipedon law. Consider the 3 rectangular forces, P, Q, and 95). On these forces construct to scale a parallelopiped. Resultant of the system is represented in magnitude and direction by the diagonal; its value is $R = \sqrt{P^2 + Q^2 + S^2}$. Its direction cosines with respect to the axes are: $\cos \alpha = P \div R$, $\cos \beta = Q \div R$, and $\cos \gamma = S \div R$.

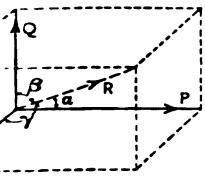

Fig 95

Resultant of any number of concurrent forces. Let the forces be specified with respect to 3 rectangular axes passing through the point of concurrency: (*a*) Resolve each force into components along the X, Y and Z-axes; (*b*) Find ebraic sums of the x, y and z components, and indicate them by ΣF_x, nd ΣF_y; (*c*) Find the resultant of these three partial resultants by the opipedon law; its value is $R = \sqrt{\Sigma F_x^2 + \Sigma F_y^2 + \Sigma F_z^2}$; its direction angles $\cos^{-1} \dfrac{\Sigma F_x}{R}$; $\beta = \cos^{-1} \dfrac{\Sigma F_y}{R}$; $\gamma = \cos^{-1} \dfrac{\Sigma F_z}{R}$

29. Moments and Couples

ent or torque of a force about a point is the product of the force mag- and the distance from the point to its action line. This perpendicular is called the arm of the force, and the point is the r center of moments. The product is the measure otational tendency of the force. The name of the moment is a combination of the names of force tance units: thus: foot-pound, inch-pound or inch- Moments tending to produce counterclockwise rota- a body will be considered positive, and clockwise e, unless contrary convention is mentioned. Thus, 96, the moment of force P about $O = +P \times OA$.

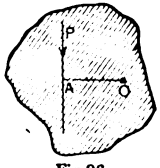

Fig 96

Moment of force about a line or axis. At any point on its action resolve the force into 2 rectangular components, one being parallel to the The product of the perpendicular component and the perpendicular dis from the axis to the force is the moment of given force about the axis. (Fig 97), $P \sin \alpha$ is the component parallel to the axis, and it has no tu effect. All the moment or turning is caused by the perpendicular component, and its value is $P \sin \alpha \times d$, being the perpendicular distance be the axis and the parallel plane ABC.

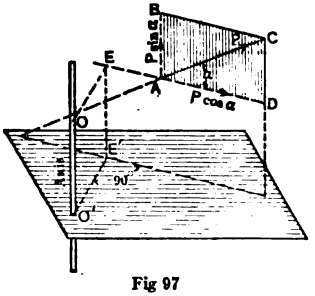

Fig 97

Principle of moments. Sum moments of any coplanar force sy about any point in their plane is eq the moment of their resultant about point. Thus (Fig 98), R is the res of P and Q, and $R \times r = P \times p - Q$ Sum of the moments of any force sy about an axis is equal to the mom their resultant about the axis. (Fig 99), R is the resultant of the 3 rectangular forces P, Q, and S. M of R about axis $X = S \times y - Q \times z$. P contributes nothing to the m sum, as it is parallel to the axis of moments. In such a case, counterclockwise moment is called positive and clockwise negative, the observer looking toward the origin O, from the positive ends of the axes. Thus, Q has positive moment about axis Z, but negative moment about axis X. Moment of a force passing through the origin of moments is zero. Moment of a force intersecting the axis of moments is zero.

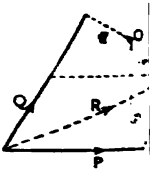

Fig 98

Couples. Two equal and parallel forces of opposite sense are called a couple. THE ARM OF THE COUPLE is the perpendicular tance between the lines of action of the forces. Moment of a couple is stant and independent of the origin of m it is equal to one of the forces times the the couple. Its sense is positive or ne according as rotational tendency is co clockwise or clockwise. Couples of equ ments, in the same or parallel planes, equivalent and may be replaced one by other. That is, a couple may be twist moved about in its plane, or transfer any parallel plane without altering the res motion of the body on which it acts.

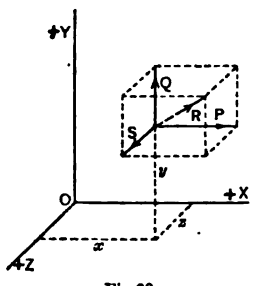

Fig 99

Resultant of any number of coplanar cou of couples in parallel planes is a couple. M ment and sense equal the algebraic sum of the ments of the component couples. A couple m represented by a vector. Length of the vector to scale represents the mag of the moment; it is drawn perpendicular to the plane of the couple from any and an arrow is placed on it to represent the way in which the couple would a right-hand screw to advance. Resultant of any number of couples (in oblique or allel planes) is a couple. The composition is effected thus: (*a*) Refer the couples to three rectangular coordinate axes. (*b*) Resolve each vector into components to the axes. (*c*) Take the sum of the components along the X, Y, and Z-axes

senting these sums by ΣC_x, ΣC_y, ΣC_z, and the resultant vector by C, its value is $\sqrt{\Sigma C_x^2 + \Sigma C_y^2 + \Sigma C_z^2}$. Its direction angles are

$$\phi_x = \cos^{-1}\frac{\Sigma C_x}{C};\ \phi_y = \cos^{-1}\frac{\Sigma C_y}{C};\ \phi_z = \cos^{-1}\frac{\Sigma C_z}{C}$$

orce may be resolved into a force acting at a chosen point and a couple. g 100, P_1 is the given force and O the n point. Through O apply a pair of forces, ite in sense, equal and parallel to P_1. As d P_3 balance, no change is produced in n of body due to the addition. P_1 and P_3 tute a couple of moment = $P \times a$, which is me as moment of P_1 about O; and P_2 is a just like P_1, but acting through the chosen O. Conversely, a force and a couple in a compound into a single force parallel to force, of same sense and magnitude, and ced that its moment about any point in action line of given force is equal ment of given couple.

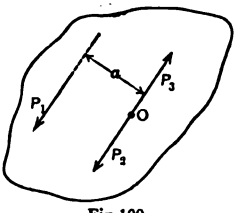

Fig 100

30. Resultants of Coplanar Nonconcurrent Forces

sultant of coplanar parallel forces may be (*a*) a single force or (*b*) a couple. **se** (*a*). Resultant is a single force. To find the resultant of the 4 par- orces shown in Fig 101:

phical solution. (*a*) Plat AB to represent magnitude and sense of ab; then BC resent magnitude and sense of bc; then CD and DE to represent the other two forces; (*b*) choose the pole O in any convenient position, and draw the rays AO, BO, CO, DO, and EO; (*c*) from any point on ab, draw strings parallel to AO and OB; from intersection of ob and bc draw oc parallel to OC until it intersects cd; from that point draw od to intersect de; then oe to intersect oa at K; (*d*) AE, from the beginning to the end of vector diagram, gives the magnitude and sense of the resultant = downward; its action line is ae, through K, parallel to AE, 5.3 ft to right of ab.

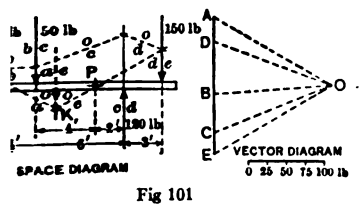

Fig 101

polygon formed on the space diagram is called a string or funicular polygon; its epresent the action lines of the components that replace the parallel forces. Thus, cting in the line bo, is replaced by BO = 140 lb, and OC = 160 lb acting in the lines l oc. AO and OE are components of the resultant AE. The object of the funic- olygon is to locate one point on the action line of the resultant.

ebraic solution. The magnitude and sense of the resultant are given by $R = \Sigma F$; ition is determined by use of the principle of moments, the moment of the result- ing equal to the algebraic sum of the moments of the forces. Hence arm = $\Sigma M \div R$. est to call upward forces positive, and distances to right of moment origin positive. lving example shown in Fig 101, tabulate the values as follows:

rce, lb	Arm from M	Moment about M	Arm from P	Moment about P
−100	0	0	−8	+800
− 50	+ 4	−200	−4	+200
+120	+10	+1 200	+2	+240
−150	+13	−1 950	+5	−750
= −180 lb	ΣM_M = −950 ft-lb		ΣM_P = +490 ft-lb	

$R = 180$ lb downward. Distance from $M = -950 \div -180 = +5.3$ ft. Dist from $P = +490 \div -180 = -2.7$ ft. Either of these distances locates the point Fig 101, and checks the graphical solution.

Case (b). $\Sigma F = 0$, and resultant is a couple.

Graphical solution. Consider the 4 parallel forces in Fig 102. The force po begins at A and ends at E. same point; hence the result not a single force (this is call closed force polygon). Const the funicular polygon as fo The first and last strings, ao oe, being parallel, do not inter The forces acting in those AO and OE, being equal opposite in sense, form a co Hence the resultant of the sy is a couple. The forces $AO = OE = 750$ lb The arm $MN = 3.67$ ft. The mom $750 \times 3.67 = 2\,752$ ft-lb. The sense, by inspection of the space diagram, is cl wise. The moment of the couple is the same, no matter what pole O is selected

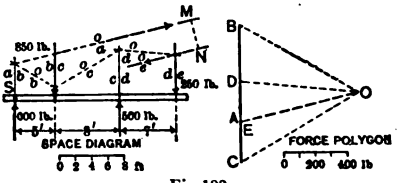

Fig 102

Algebraic solution of the same example (see table):

Forces, lb	Arm from S	Moment about S
+600	0	0
−850	+ 5	−4 250
+500	+13	+6 500
−250	+20	−5 000
$\Sigma F = 0$		$\Sigma M_s = -2\,750$ ft-l

Hence the resultant is a clockwise couple of moment equal to 2 750 ft-lb. Since couples of equal moment and sense in the same plane are equivalent, it is unnecessary to give more detail.

Special cases. Two parallel forces. Case (a). Forces alike in sense. Given the 2 forces P and Q, locate Fig 103. The resultant lies between these forces, and is equal in magnitude to P The action line of the re ant is found from the equa $a = (Q \times b) \div P$. Case Forces opposite in sense. the 2 forces P and Q as Fig 104. Resultant lies outside the forces P and Q, is adja to the larger force, and is in magnitude to $Q - P$. action line of the resultan found from the equation, $s = (Q \times b) \div P$. The sense of the resultant is the same that of larger force. In either case, the resultant divides the distance between forces into segments inversely proportional to the adjacent forces; or

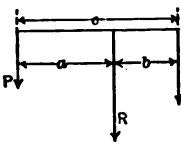

Fig 103

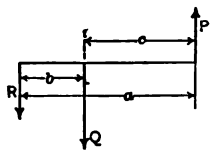

Fig 104

$$P \div b = Q \div a = R \div c.$$

Resultant of coplanar nonconcurrent forces. Case (a). Resultant equals a single force.

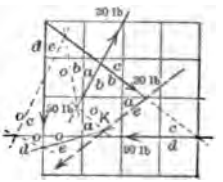

Fig 105

Graphical Solution. Construct a force polygon as if the forces were concurrent. The closing line gives the magnitude, sense, and angular direction of the resultant. The action line is found drawing a funicular polygon. Thus, to find the resultant of the 4 forces in Fig 10 Construct the force polygon $ABCDE$; (b) choose a convenient pole O, and draw rays; (c) start at any point on ab and draw the funicular polygon; (d) determine K

ection of the first and last strings. This is one point on the action line of the re-
nt. Resultant = AE = 67 lb, downward to the left, at angle $\theta = \tan^{-1}\frac{0.784}{1.0} =$
' to horizontal. Action line is ae, parallel to AE, through K.
ond graphical method. Use the triangle law to find the resultant of two forces.
he same law to find the resultant of this partial resultant and the third force.
nt until the final resultant is obtained.
ebraic solution. The resultant is found in
itude, sense, and angular direction as if the
were concurrent.

$$\sqrt{\overline{\Sigma F_x}^2 + \overline{\Sigma F_y}^2}, \quad \cos\theta = \frac{\Sigma F_x}{R}, \quad \sin\theta = \frac{\Sigma F_y}{R}$$

ich θ is the angle between R and the X-axis,

that the sign of its moment is the same as that
f. As an example, find the resultant of the 3
in Fig 106.

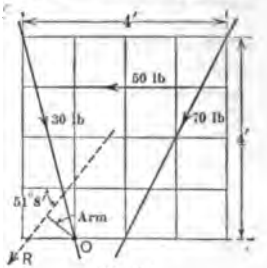

Fig 106

Force, lb	F_x, lb	F_y, lb	M_o, ft-lb
50	−50	0	+150
70	−31.3	−62.6	− 62.6
30	+ 7.3	−29.1	0
	$\Sigma F_x = -74$	$\Sigma F_y = -91.7$	$\Sigma M_o = 87.4$ ft-lb

$R = \sqrt{(74)^2 + (91.7)^2} = 118$ lb downward to the left.

ngle with X-axis = $\tan^{-1}\frac{91.7}{74} = 51° 8'$. Arm about $O = 87.4 \div 118 = 0.74$ ft.

s case, R is to the left of O because its moment must be = $\Sigma M_O = +87.4$ ft-lb
se (b). Resultant is a couple.

phical solution. Let forces N, P, Q, T, and S (Fig 107) represent a system of
the force polygon of which closes, and which reduces to the 2 components AO and
OF, acting in ao and of. Since these components are equal, opposite and parallel, the resultant is a couple. The arm of the couple is the perpendicular distance MN, between the first and last strings. The moment is the product of OA (according to force scale) and the arm MN (according to scale of space diagram). The sense of the couple is counterclockwise, as found by inspection of the space diagram.

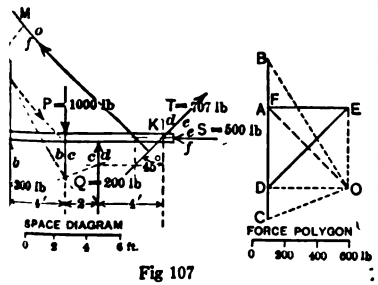

Fig 107

The moment = 710 × 3.1
= 2 200 ft-lb.

ebraic solution. Any couple the moment of which equals the algebraic sum of
oments of the given forces about any point may be regarded as the resultant. In
7, assume forces acting as indicated. The algebraic sum of the x and y compo-
is zero. Taking moments about point K,

$$\Sigma M_K = 1\,000 \times 6 - 300 \times 10 - 200 \times 4 = +2\,200 \text{ ft-lb}.$$

Hence, the resultant of the system is a couple, of moment equal to 2 200 ft-lb and counterclockwise sense.

31. Resultants of Noncoplanar Nonconcurrent Forces

Resultant of noncoplanar parallel forces. The possible resultants a single force or a couple.

Choose a set of 3 rectangular axes, with the Z-axis parallel to the forces, let the positions of the forces be specified by the x and y coordinates of action lines. As an example, consider the parallel forces shown in Fig 108 to be perpendicular to plane of the paper. Tabulate the computations as below:

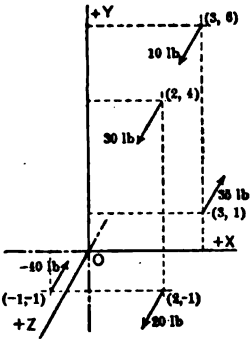

Fig 108

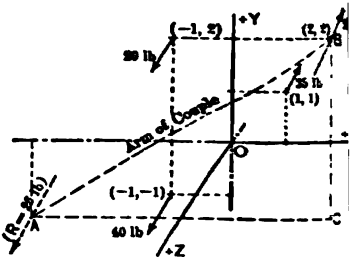

Fig 109

Force, lb	x, ft	y, ft	M_x or $F \times y$, ft-lb	M_y or $F \times x$,
+10	+3	+6	+ 60	+30
+30	+2	+4	+120	+60
+20	+2	−1	−20	+40
−40	−1	−1	+40	+40
−35	+3	+1	−35	−105
ΣF = −15 lb			ΣM_x = +165	ΣM_y = +65

$R = \Sigma F = -15$ lb, in the $-Z$ sense, or backward. $x_0 = \dfrac{\Sigma M_y}{\Sigma F} = \dfrac{+65}{-15} = -4.33$ ft. $y_0 = \dfrac{\Sigma M_x}{\Sigma F} = \dfrac{+165}{-15} = -11$ ft. Hence the coordinates of the action line of the result are x_0, y_0, or (−4.33 ft, −11 ft). Position of the resultant is not indicated in Fig In the above computation, the algebraic rules of signs for multiplication and division followed throughout, so that the values of x_0 and y_0 may be interpreted algebraically. This method agrees with the usual convention of signs for computing moments about the X-axis, but is the reverse of the usual convention for moments about the Y-axis.

If $\Sigma F = 0$, and if ΣM_x or ΣM_y does not equal zero, the resultant is a couple and not a force. The plane of the couple will be parallel to the Z-axis. It is necessary to determine the moment of the couple, its sense, and the inclination of its plane with the plane. Consider the 4 forces in Fig 109 as an example:

Force, lb	x, ft	y, ft	M_x, ft-lb	M_y, ft-lb
+20	−1	+2	+40	−20
+40	−1	−1	−40	−40
−35	+1	+1	−35	−35
−25	+2	+2	−50	−50
ΣF = 0			ΣM_x = −85	ΣM_y = −145

$\Sigma F = 0$, the resultant of all except one of the forces, with the omitted force, is e. Omitting the last force, $R = \Sigma F = +25$ lb. Its $x_0 = \frac{\Sigma M_y}{\Sigma F} = \frac{-95}{+25} = -3.8$ ft, $= \frac{\Sigma M_x}{\Sigma F} = \frac{-35}{+25} = -1.4$ ft. AB is the arm of the couple, and from the triangle s length is found to be 6.72 ft. The moment of the couple $= 25 \times 6.72 = 168$ BAC is angle its plane makes with horiz plane. Angle $BAC = \tan^{-1}\frac{3.4}{5.8} = 30° 21'$. the couple from plus end of Y-axis, its sense is observed to be counterclockwise.

ultant of noncoplanar nonconcurrent nonparallel forces is gener- single force acting at a chosen point and a couple not coplanar with the The magnitude, sense, and angular direction of the single force is the s if the forces were concurrent.

$$\sqrt{(\Sigma F_x)^2+(\Sigma F_y)^2+(\Sigma F_z)^2};\ \phi_x = \cos^{-1}\frac{\Sigma F_x}{R};\ \phi_y = \cos^{-1}\frac{\Sigma F_y}{R};\ \phi_z = \cos^{-1}\frac{\Sigma F_z}{R}$$

acts through the selected origin of reference. To determine the couple, te the sums of the moments of the forces about the coordinate axes of ce. These moment sums represent 3 couples, which are axial compo- f the resultant couple. Consider ΣM_x as a vector along the X-axis, ΣM_y ctor along Y, and ΣM_z along Z. The moment of the resultant couple $\sqrt{(\Sigma M_x)^2 + (\Sigma M_y)^2 + (\Sigma M_z)^2}$, and the direction angles of its vector are

$$\theta_x = \cos^{-1}\frac{\Sigma M_x}{C};\ \theta_y = \cos^{-1}\frac{\Sigma M_y}{C};\ \theta_z = \cos^{-1}\frac{\Sigma M_z}{C}$$

d C may be compounded into 2 forces which do not intersect. In a special a R might be zero or C might be zero. This means the resultant might uple only, or might be a single force.

32. Conditions of Equilibrium

dy is in equilibrium with respect to adjacent bodies if it remains at rest spect to them, or if it moves at constant velocity; that is, its state of does not change. A force system is in equilibrium if its resultant is Such a system causes no change in the state of motion of the body to t is applied. If a body is in equilibrium with respect to adjacent bodies, e external force system applied to it is in equilibrium. By this external stem is meant the pull of gravity and all the pulls or pushes exerted on ly by other bodies.

nding on the kind of force system involved, varying numbers of tests litions must be applied to prove that the system is in equilibrium, or resultant exists. In the usual problem, a body is known to be in equi- ; hence the system composed of all the external forces acting upon it e in equilibrium. In such case the tests are not needed to ascertain if ium exists; but they are used to set up relations involving unknown distances, or angles, and the unknown elements are then computed d they are not too numerous. Such computations are conducted either ically or graphically. (See following table.)

ial conditions of equilibrium. If 3 forces are in equilibrium they e coplanar, and must be concurrent or parallel; if concurrent, each proportional to the sine of the angle between the other two; if parallel, ce is proportional to the distance between the other two. If a force is in equilibrium, the resultant of any part must balance the resultant ther part.

Necessary and sufficient independent conditions of equilibrium for the vari force systems

	System	Algebraical		Graphical	
		No	Conditions	No	Conditions
Coplanar	Collinear	1	$\Sigma F = 0$	1	Force polygon
	Concurrent at point O	2	$\Sigma F_x = 0$, $\Sigma F_y = 0$, if the angle between x and y does not equal 180°; or, $\Sigma F_x = 0$, $\Sigma M_a = 0$, if x direction is not perpendicular to aO; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if aOb is not a straight line	1	Force polygon c
	Parallel	2	$\Sigma F = 0$, $\Sigma M = 0$; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if line ab is not parallel to forces	2	Force and fu lar polygons Last item first ar strings con
	Nonparallel nonconcurrent	3	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma M = 0$; or, $\Sigma F_x = 0$, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if x is not perpendicular to ab; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, $\Sigma M_c = 0$, if abc is not a straight line		Force and fun polygons clos
Noncoplanar	Concurrent at point O	3	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma F_z = 0$; or, ΣF_s in every direction and ΣM about every axis = 0. Combinations of moment and resolution equations can be arranged, but are not common	2	Force polygon It is warped plan and must show Not com used
	Parallel	3	$\Sigma F_z = 0$, $\Sigma M_x = 0$, $\Sigma M_y = 0$, forces parallel to z-axis. Other combinations possible but not common		Not used
	Nonconcurrent nonparallel	6	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma F_z = 0$, $\Sigma M_x = 0$, $\Sigma M_y = 0$, $\Sigma M_z = 0$. ΣM about every axis = 0, and it is often convenient to employ more than three moment equations, instead of using so many resolution equations		The projecti system plane is librium. braical cal condi be used such proje tems

33. Equilibrium Problems

General method of solution. (*a*) Sketch or specify the free body in equilibrium, and indicate the complete external force system acting (*b*) Discuss the problem as to number and kinds of unknown quan see if a solution is possible. If the first system tried cannot be solved, the original body discussed (say some machine) into simpler parts, and

cuss them until one is found that permits of solution. (*c*) Apply the iate conditions of equilibrium and solve for the unknown forces, angles, nces. (*d*) Make use of the acquired information to solve other sys- there are any others.

olution equations are used, it is desirable each time to resolve perpen- to one of the unknown forces, so as to avoid the solution of simultaneous ns and to make the answers independent of each other. If moment are used, it is best to select them on the action lines of some of the un- forces. If moment axes are used they should be selected so as to inter- ne of the unknown forces.

rtain equilibrium problems often occur in practice, it is convenient to hem into typical problems, and to detail the method of solution of each.

cal problem I. A SYSTEM OF COPLANAR CONCURRENT FORCES is in ium and all but two are known; the action lines of these are known; l their magnitudes and senses. ALGEBRAIC SOLUTION. (*e*) Assume senses h unknown forces. (*c*) Write a pair of equilibrium equations involving nown forces, and solve for the two unknowns. A plus answer indicates se correctly assumed. A minus answer indicates incorrect assumption. CAL SOLUTION. (*f*) Letter the action lines of the wholly known forces, en the action lines of the two unknown forces. (*g*) Draw the force to the end of the last known vector, and close it by drawing parallels nknown forces through the ends of the first and last vectors, and mark rsection of these lines as the last vertex in the polygon. (*h*) The senses ad confluently from starting point back to same point, the last two vectors ting the two unknown forces in magnitude and sense.

ple. Two smooth cylinders rest upon a 30° plane and against a vertical wall as Fig 110. Determine all forces acting on each cylinder. (*a*) The forces involved lb, 200 lb, *P*, *Q*, *R*, and *S*, the last g normal to the surfaces of contact surfaces). (*b*) Consider the two as a single free body. The external tem is 100 lb, 200 lb, *P*, *R*, and *S* are internal). The system is non- nt, so does not come under typical I. Consider the large cylinder as a . The external force system is 100 and *S*. While this system is con- it can not be solved because there than two unknown quantities. Next the small cylinder as a free body. e system is 200 lb, *P* and *Q*, and pical problem I. ALGEBRAIC SOLU- hoose *X* and *Y* directions parallel

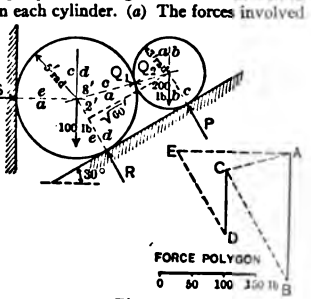

Fig 110

ndicular to the plane. By (*c*) and (*e*), $\Sigma F_x = 0 = Q_1 \frac{\sqrt{60}}{8} - 200 \sin 30°$. Hence

$= 103.3$ lb. $\Sigma F_y = 0 = P - 200 \cos 30° - 103.3 \times \frac{6}{8}$. Hence $P = 199$ lb.

ider the large cylinder as a free body. $Q_1 = Q_2 = 103.3$ lb. Use the same

directions. $\Sigma F_x = 0 = S \cos 30° - 103.3 \times \frac{\sqrt{60}}{8} - 100 \sin 30°$. Hence,

lb. $\Sigma F_y = 0 = R - 100 \cos 30° - 173.2 \sin 30° + 103.3 \times \frac{6}{8}$. Hence $R =$

GRAPHICAL SOLUTION. Discussions (*a*) and (*b*) are same as above. The free small cylinder. The force system is 200 lb, *ab*, *bc*, and *ca*, and the polygon le *ABC* (Fig 110). $BC = 199$ lb, $CA = 103.3$ lb. Next, consider the large cylin- body. The force system is *ac*, *cd*, *de* and *ea*. Plat the known forces *AC* and

CD. From *D* draw *DE* parallel to *de*, and from *A*, *AE* parallel to *ae*; these lines i sect at *E*. *DE* = 147.4 lb, and *EA* = 173.2 lb are the magnitudes and senses of the unknowns.

If the system is concurrent and all the forces are known except one, the two unk elements will be one angle and one magnitude and sense. Both may be determ writing the equilibrium equations, or by drawing the force polygon.

Typical problem II. A SYSTEM OF COPLANAR PARALLEL FORCES is in librium and all are known except two; the action lines of these two are k required their magnitudes and senses. ALGEBRAIC SOLUTION. (*e*) Assume s for both unknown forces. (*c*) Write a pair of equilibrium equations in the unknown forces and solve for the two unknowns. A plus answer in the sense correctly assumed. A minus answer indicates incorrect assu As a check on the results apply a third equilibrium equation. For pr of this type the algebraic solution is preferable to the graphical. GRAP SOLUTION. (*f*) Letter the action lines of the wholly known forces and the action lines of the two unknown forces. (*g*) On a line of indefinite parallel to the forces, often called the load line, form the force poly plotting vectors of the known forces continuously to end of last known The vector of the first unknown force extends from this point to so known point on the load line. The unknown point is to be found. struct a funicular polygon. Draw first string between first known for last-lettered unknown force. Continue funicular polygon to intersec last known string with first-lettered unknown force. Draw closing strin this point, to intersection of first string with last-lettered unknown force. a ray through pole parallel to closing string; its intersection with the k is the point sought. senses must read out from the starting po to the same point. T two vectors repres two unknown forces nitude and sense.

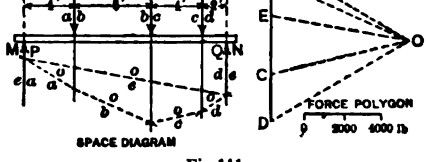

Fig 111

Example. A beam as shown in Fig 111 a ported at the points M Determine the reactions supports. (*b*) Consider th as a free body. The external force system consists of the forces 1 000 lb, 5 2 400 lb, *P*, and *Q*. This is a coplanar parallel system and is typical par ALGEBRAIC SOLUTION. (*c*) Assume senses for the reactions. By (*c*),

$$\Sigma M_M = 0 = -4 \times 1\,000 - 10 \times 5\,000 - 14 \times 2\,400 + 16\,Q = 0$$

Hence $Q = 5\,475$ lb; correct sense was assumed.

$$\Sigma M_N = 0 = 2 \times 2\,400 + 6 \times 5\,000 + 12 \times 1\,000 - 16\,P = 0$$

Hence $P = 2\,925$ lb; correct sense assumed. As a check, apply condition, $\Sigma F =$

$$\Sigma F = 0 = -5\,475 + 1\,000 + 5\,000 + 2\,400 - 2\,925 = 0$$

GRAPHICAL SOLUTION of the same problem involves the construction of a cl polygon and a closed funicular polygon. Draw vectors *AB*, *BC*, *CD* to re lb, 5 000 lb, 2 400 lb. Let *DE* represent *Q* and *EA* represent *P*. The problem point *E*. This is done with the aid of the funicular polygon. Draw the ra *OC*, and *OD*. Start on the action line of *P* and draw the string polygon. T line is *oe*. Draw the ray *OE* parallel to *oe*. The unknown reactions are *D*

(**Note.** — This principle can not be applied to beams having more than tw support. Such problems require special treatment.)

Typical problem III. A SYSTEM OF COPLANAR NONCONCURRENT PARALLEL FORCES is in equilibrium, and all are known except two; th

f one of these and a point in the action line of the other are known. De-
ne the magnitude and sense of the one, and the magnitude, sense, and
ir direction of the other. ALGEBRAIC SOLUTION. (*e*) Assume sense for
nknown force. (*c*) Write a moment equation, center of moments be-
given application point, to find first unknown force. (*e'*) Assume sense
ngular direction for second unknown force. (*c*) Write a pair of equilib-
equations involving the magnitude and angular direction of the second
wn force and solve for the two unknown quantities. A plus answer for
agnitude indicates the sense correctly assumed. A plus answer for the
ir direction indicates it correctly assumed. A minus answer for either of
antities indicates incorrect assumption for the one involved. Check re-
y means of an additional equilibrium equation. GRAPHICAL SOLUTION.
tter the action lines of the wholly known forces, then the action line of
st unknown, and finally the force passing through the given application
(*g*) Draw the force polygon for the known forces. Through the end of
t vector draw a line parallel to the action line of the first unknown force.
: a pole and draw the rays. (*i*) Construct a funicular polygon, passing
st string through the application point of the second unknown force,
aking the last, or closing, string, pass through the same point. Draw
through the pole, parallel to closing string; its intersection with the
drawn parallel to first unknown is last vertex in the force polygon.
this point, draw the closing line of the force polygon. (*h*) The senses
ead confluently from start-
at back to same point. The
o vectors represent the two
wn forces.

). This is typical problem III.
AIC SOLUTION. (*e*) Assume P
By (*c*),

$= 0 = 20\,000 \times 18 + 25\,000 \times$
$30° - 36P$

$P = 24\,430$ lb; correct sense

ssume Q upward to the left at
vith horizontal. By (*c*),

$0 = 25\,000 \sin 30° - Q \cos\theta, \quad \Sigma F_y = 0 = 25\,000 \cos 30° + 20\,000 - 24\,430 - Q \sin\theta$

simultaneously, $Q = 21\,300$ lb, and $\theta = 54°$. Sense and direction were cor-
sumed, hence Q acts upward to the left at 54° to the horiz. GRAPHICAL SOLU-
ab and *bc* are the action lines of the given loads, *cd* of the reaction P and *da*
action Q. (*g*) Draw the vectors AB and BC, and a line through C, parallel to
ose a pole and draw the rays. (*i*) Construct the funicular polygon, drawing
gh M, and draw closing string *od* from K to M. Draw OD through O to inter-
at D. Draw DA. (*h*) Vectors CD and DA represent the two unknown forces,
,30 lb and $Q = 21\,300$ lb. The action line of Q is *da*, making angle with
54°.

Typical problem IV. A SYSTEM OF COPLANAR NONCONCURRENT N PARALLEL FORCES is in equilibrium and all except three are wholly known; action lines of these three are known; required their magnitudes and sen ALGEBRAIC SOLUTION. (*e*) Assume senses for the unknown forces. (*c*) determine first unknown force, write a moment equation, center of mom at intersection of action lines of other unknown forces. (*c*) Write a pai equilibrium equations involving the other two unknowns and solve for th Check results by means of an additional equilibrium equation. GRAPH SOLUTION. Assume any two of the unknown forces replaced by their resul at the point where their action lines intersect. This resultant, the third known force, and the known forces are in equilibrium and correspond to ty problem III. Proceed as specified in (*f*), (*g*), (*i*) and (*k*) for typical problem to determine the resul and the third unknown f (*j*) Resolve the resultan the selected two unkn forces into component allel to their action lines, determining their mu tudes and senses.

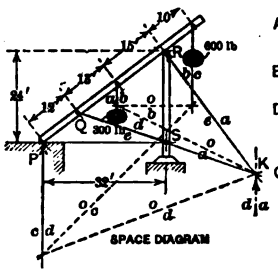

Fig 113

Example. The bar *PR* (Fig 113), resting against a wa floor at *P* and against a sm post at *R*, is held by an ins cord *QS* and carries two l Neglect the weight of the and determine the forces a on the bar at *P* and *R*, and the tension in the cord *QS*. (*a*) The external forces a on the bar are the given loads, the reaction of the support at *P* (vertical on accou smooth surface), the reaction of the post at *R* (normal to the bar on account of sm surface), and the pull of the cord at *Q* (direction is *QS*). (*b*) The unknown force the reactions *P* and *R*, and the tension *Q*. This is typical problem IV. ALGEBRAIC TION. (*e*) Assume *P* upward. By (*c*),

$$\Sigma M_K = 0 = 300 \times 35.6 + 600 \times 15.6 - P \times 55.6$$

Hence, $P = 360$ lb; correct sense assumed. Choose *X* and *Y* directions paralle perpendicular to the bar. (*e*) Assume *R* upward to the left on bar, *Q* downw right. By (*c*),

$$\Sigma F_x = 0 = 300 \times \tfrac{3}{5} + 600 \times \tfrac{3}{5} - 360 \times \tfrac{3}{5} - Q\tfrac{13.6}{23.5}$$

Hence $Q = 560$ lb; correct sense assumed.

$$\Sigma F_y = 0 = 300 \times \tfrac{4}{5} + 600 \times \tfrac{4}{5} + 560 \times \tfrac{19.2}{23.5} - 360 \times \tfrac{4}{5} - R$$

Hence $R = 890$ lb; correct sense assumed.

As a check, apply condition, $\Sigma M_Q = 0$.

$$\Sigma M_Q = 890 \times 28 - 360 \times \tfrac{4}{5} \times 12 - 300 \times \tfrac{4}{5} \times 13 - 600 \times \tfrac{4}{5} \times 38 = 24\,900 - 22\,$$

GRAPHICAL SOLUTION. Assume *Q* and *R* replaced by their resultant. Its act passes through point *K*. (*f*) *ab* and *bc* are the action lines of the given loads, reaction *P*, and *da* of the resultant of *Q* and *R*. (*g*), (*i*), and (*k*). Draw fu funicular polygons to determine the unknown vectors *CD* and *DA*. *CD* re reaction $P = 360$ lb. (*j*) Resolve *DA* into components *DE* and *EA*, parallel t lines *de* and *ea* of *Q* and *R*. (*k*) Vectors *DE* and *EA* represent the other tw forces, $Q = 560$ lb, and $R = 890$ lb.

General noncoplanar system. Example. The crane (Fig 114), is supported socket at the foot of the post at *D*, is kept from overturning by the back-stays *A*

and carries a load of 600 lb. , F, G, D, are in the vertical XY-.) Determine the axial compo- of the reaction on the post at D he tensions in the back-stays. (b) external forces acting on the post e load, the reaction at D, and the ns in the back-stays at A. The n of forces is noncoplanar, non- rrent, nonparallel. Moment equa- are the most convenient to apply is solution. By (c),

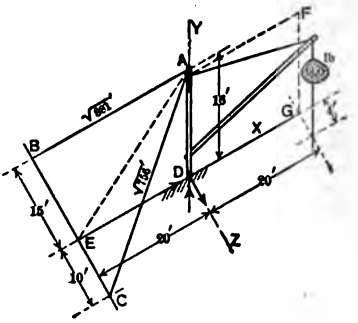

Fig 114

$$\Sigma M_y = 0; \quad D_y = \frac{600 \times 40}{20} = 1\,200 \text{ lb.}$$

$$\Sigma M_z = 0; \quad D_z = \frac{600 \times 20}{16} = 750 \text{ lb.}$$

$$\Sigma M_x = 0; \quad D_x = \frac{600 \times 4}{16} = 150 \text{ lb.}$$

$$\Sigma M_{x_C} = 0 = AB \times \frac{16}{\sqrt{881}} \times 25 - 1\,200 \times 10 + 600 \times 6, \qquad AB = 624 \text{ lb.}$$

$$\Sigma M_{x_B} = 0 = AC \times \frac{16}{\sqrt{756}} \times 25 + 600 \times 19 - 1\,200 \times 15; \qquad AC = 454 \text{ lb.}$$

senses of the components of the reaction at D are shown in Fig 114.

FRICTION

34. Definitions

rfectly smooth surface is one that offers no resistance to the sliding of y upon it. The force exerted by such a surface is normal to the surface tact. If the surface is rough, the resultant thrust of the surface is oblique, called the TOTAL REACTION. The tangential component of the total re- is called FRICTION and the normal component is called NORMAL REACTION. on is a passive resistance, and is developed as it is needed to prevent n. For friction to exist there must be a tendency for a body to slip over ace, due to the fact that the resultant of all the applied forces acting on dy (omitting total reaction of the surface) has a component parallel to rface. If the surface is smooth, such a component causes motion of the If the surface is rough, it exerts a frictional force upon the body which lizes the tendency to move. For any given conditions, there is a limit amount of friction, reached when slipping impends, called LIMITING ON. When the limiting friction is attained the angle between the total n and the normal to the surface is the ANGLE OF FRICTION. In case a no slipping, friction is called STATIC, and may have any magnitude from o the limiting friction, depending upon the tendency to move. If this cy to move exceeds limiting friction, the body slips and KINETIC FRICTION pposes motion; its value is less than limiting static friction.

fficient of friction is the ratio of the limiting friction to the correspond- rmal reaction. If the angle of friction be ϕ, the normal reaction N, the g friction F', and the coeff of friction f, then $f = \tan \phi = F' \div N$. If a e placed upon an inclined plane, the angle of inclination for which slip- f the body impends is the ANGLE OF REPOSE for the two rubbing surfaces qual to the angle of friction.

35. Friction Cone

Consider a body, resting on a rough plane, to be acted upon by several f
(Fig 115). Draw the normal OP to the surface at the point where the re
of all the applied forces, except the total reaction, cuts the surface; the
OQ, making the angle ϕ with the normal equal to the angle of friction.
cone generated by revolving OQ about the axis OP, is the CONE OF FRICT
The body will not slip if the resultant of all applied forces lies within this
it will slip if the resultant lies outside.

site in sense to the resultant. Its
ponents, parallel and normal
surface, are DE and EA. Fro
the body is DE = 23 lb, upward
the surface, and the normal re
EA = 120 lb, upward normal
surface.

From the algebraic viewpoint,
normal reaction on the surface is

$$N = 150 \cos 30° + 20 \sin 30° - 40 \sin 30° = 120 \text{ lb}$$

Available or limiting friction = $\frac{1}{4} \times 120 = 30$ lb. Sum of the components parallel to the plane = $150 \sin 30° - 20 \cos 30° - 40 \cos 30° = 23$ lb, downward. If needed, the surface can supply 30 lb of friction; it actually does supply 23 lb acting upwards on the body to preserve equilibrium.

36. Friction Circle

The reaction of a bearing on a journal is usually assumed to pass through the center of the journal. If the bearing is worn (as shown much exaggerated in Fig 116, for the journal A), the action line of the reaction still passes through center A if the surfaces are smooth. Otherwise, when slipping impends, the action line makes the friction angle ϕ with the normal AD to the contact surfaces on the line of contact between the journal and the bearing. If motion impends for clockwise rotation of the journal, DB is the action line; if for counterclockwise rotation, it is EC. If r be the journal radius, the perpendicular to the action lines from the journal center is AB or $AC = r \sin \phi$. For a given journal and bearing, this value is constant and may be represented by the radius of a circle with center at A. This is the FRICTION CIRCLE, and the bearing reaction is always tangent to it if slipping impends. For practical conditions, angle ϕ is so small that $r \tan \phi = r \sin \phi$ (approx). Radius of the friction circle may be taken as $r \times f$, nearly.

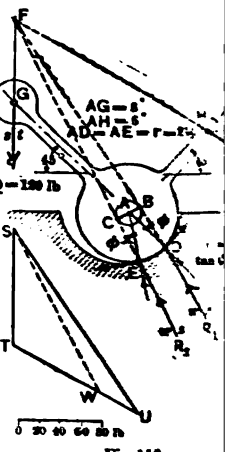

Fig 116

In a given problem, it is often impossible to observe D, the line of contact between

al and bearing, but the action line of the bearing reaction must be tangent e friction circle. Other known conditions may fix another point in this i line so that its position is readily found.

Fig 116, with data as given, find what force P is needed to overcome Q (motion im- ig for clockwise rotation). The journal is under the action of 3 forces, P, Q, and R, rrent at F. As R must be tangent to the friction circle, its action line is either FD . The correct position is determined by resolving R into tangential and normal nents, and making the choice so that friction opposes impending motion. The olygon for the 3 forces is STU; then $R_1 = US = 226$ lb, and $P = TU = 142$ lb. greatest force P which Q can overcome (motion impending for counterclockwise n), is found from the triangle STW, corresponding to R_2; then $R_2 = WS = 188$ lb, $= TW = 96$ lb.

37. Coefficients of Friction

fficients of static friction depend upon character of the surfaces, kind iterial and lubricant used. Recent experiments prove that the coeff of friction is not independent of the normal pressure on the contact surfaces, the time of contact between the surfaces.

38. Belt or Coil Friction

band is placed about a rough cylinder and a tensile force applied to each hese forces may be very unequal without causing slipping of the band the cylinder, and are unequal even if slipping occurs. The band may be rope, or brake band, while the cylinder may be a pulley or sheave, post, n, or similar device.

T_1 be the larger of the forces acting upon the band, T_2 the smaller one, correspond- the tensions in the tight and loose sides of a belt; and W the friction between band

and cylinder. Then, $W = T_1 - T_2$. Let the arc covered by the band subtend an α at the center of the cylinder, α radians = (α degrees $\times \pi$) ÷ 180; e (= 2.718) the base of the Naperian system of logarithms, and f the coeff of friction, care being to select a suitable value for either static or kinetic friction, depending on whether not slipping occurs. Then, $T_1 = T_2 e^{f\alpha} = T_2 10^{\frac{\pi}{180}(0.434)\, f\alpha^\circ}$. The first α is expressed in radians, the last α in degrees. For belting, the coeff of friction is often taken as

CENTERS OF GRAVITY

39. Centroid and Center of Gravity

Centroid of a system of parallel forces with fixed application points is the point through which their resultant always passes, no matter how the forces may be turned (but still remaining parallel). The force of gravitation acting on the particles of a body constitutes a system of forces practically parallel, and the centroid of these forces is the CENTER OF GRAVITY of the body. Referring the application points of such a force system to a set of coordinates, the coordinates of the centroid, or center of gravity, are given by:

$$\bar{x} = (\Sigma F \cdot x) \div \Sigma F, \quad \bar{y} = (\Sigma F \cdot y) \div \Sigma F, \quad \bar{z} = (\Sigma F \cdot z) \div \Sigma F$$

In these equations F represents one force (or the weight of one particle), x the distance of its application point from the YZ-plane.

If the body is composed of parts of known weight, and the positions of the centers of gravity are known, the coordinates of the center of gravity of the whole body are:

$$\left.\begin{aligned} \bar{x} &= \frac{w_1\bar{x}_1 + w_2\bar{x}_2 + w_3\bar{x}_3 + \cdots}{w_1 + w_2 + w_3 + \cdots} \\ \bar{y} &= \frac{w_1\bar{y}_1 + w_2\bar{y}_2 + w_3\bar{y}_3 + \cdots}{w_1 + w_2 + w_3 + \cdots} \\ \bar{z} &= \frac{w_1\bar{z}_1 + w_2\bar{z}_2 + w_3\bar{z}_3 + \cdots}{w_1 + w_2 + w_3 + \cdots} \end{aligned}\right\} \quad (A)$$

ich w_1 represents the weight of one part and $\bar{x}_1$, $\bar{y}_1$, $\bar{z}_1$, are the coordinates of nter of gravity. Any one of the above expressions may be read as, "the of the moments divided by the sum of the forces."

in formulas (*A*) the weights are replaced by volumes, areas, surfaces, or hs of lines, they determine the coordinates of the centroids, or centers of ty, of the volumes, areas, surfaces, or lines. These centroids are often l the centers of gravity of the corresponding magnitudes.

nter of gravity of part of a body remaining after certain parts have taken away is determined by the rule: The moment of the remainder of a with respect to any plane, equals the moment of the whole body minus oments of the parts taken away.

40. Formulas

ntroids of lines and areas. CIRCULAR ARC (Fig 117). Centroid is e axis of symmetry; its distance from the center is $\bar{x} = \frac{r \times c}{s} = \frac{r \sin \alpha}{\alpha}$, ig in radians. For a semicircle, $\bar{x} = 2r \div \pi$; for a quadrant, $\bar{x} = 2r\sqrt{2} \div \pi$. IGLE. Centroid of a triangle is at the intersection of the medians; its

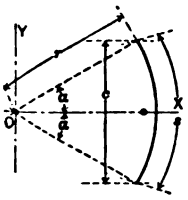

Fig 117

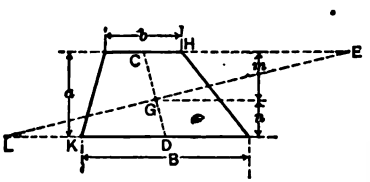

Fig 118

ndicular distance from any side equals one-third the altitude measured that side. TRAPEZOID (Fig 118). Centroid lies on the median *CD* (join- le middle of the parallel sides), at a point *G* located by following equations:

$$m = \frac{a\,(2B + b)}{3\,(B + b)}; \quad n = \frac{a\,(B + 2b)}{3\,(B + b)}$$

ocate the centroid graphically, make $HE = B$, $= b$. Draw *LE*, and the median *CD*; they in- ct at *G*, the centroid. QUADRILATERAL (Fig . Divide each side of the quadrilateral *ABCD* thirds, and through the third points draw *ef*, m, and *no*. These lines form a parallelogram, liagonals of which intersect at *G*, the centroid of quadrilateral. SECTOR OF A CIRCLE (Fig 120). roid is on the axis of symmetry; its distance the center is $\bar{x} = (2rc) \div (3s)$. For a semicircle, $4r \div 3\pi$. For a quadrant $\bar{x} = 4r\sqrt{2} \div 3\pi$; and

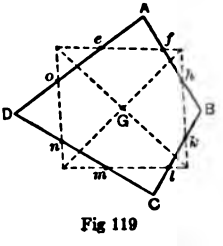

Fig 119

the distance from each bounding radius = $4r \div 3\pi$. SEGMENT OF A CIR (Fig 121). Centroid is on the axis of symmetry; its distance from the ce is $\bar{x} = (c^3 \div 12A)$, in which A is the area of the segment = $\frac{r^2}{2}(2\alpha - \sin$ α being in radians.

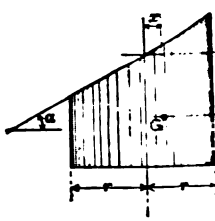

Fig 122

Centers of gravity of volumes. RIGHT CIRCULAR CYLINDER (Fig 1 Base is normal to the axis; top makes an angle α with base; mean height radius of base = r. If $\bar{y}$ is the distance of the center of gravity G from base, and $\bar{x}$ is the distance to the right of the vertical center line,

$$\bar{x} = \frac{r^2 \tan \alpha}{4h}; \text{ and } \bar{y} = \frac{h}{2} + \frac{r^2 \tan^2 \alpha}{8h}$$

FRUSTUM OF A CIRCULAR CONE. Let R = radius of the larger base and r ra of the smaller base; a = the altitude. Distance of the centroid of the cu surface from large base is $\frac{a(R+2r)}{3(R+r)}$ and from the smaller base $\frac{a(2R-}{3(R-}$ Distance from the center of gravity of the solid frustum to larger bas $\frac{a(R^2+2Rr+3r^2)}{4(R^2+Rr+r^2)}$. CONE AND PYRAMID. Centroid of the surface (base cluded) is on a line joining the apex with the centroid of the perimeter o base, at a distance of two-thirds its length from the apex. Center of gravi the solid cone or pyramid is on the line joining the apex with the centroid o base, at a distance of three-fourths its length from the apex. FRUSTUM A PYRAMID. If the frustum has regular bases, let R and r be lengths of the of the larger and smaller bases, and h the altitude. Distance of the centro the surface (bases excluded) from the larger base is $\frac{h(R+2r)}{3(R+r)}$. For any let A and a be the areas of large and small bases and h the altitude; the dis of center of gravity from the larger base is $\frac{h(A+2\sqrt{Aa}+3a)}{4(A+\sqrt{Aa}+a)}$. Sim Centroid of the surface of any zone of a sphere is midway between the Distance of the center of gravity of a solid segment from the base is $\frac{h(4r-}{4(3r-}$ where r = radius of the sphere, and h = height of the segment. For a hemis this distance is $3r \div 8$. Distance of center of gravity of a solid secto center of the sphere = $\frac{3}{8}(1+\cos\alpha)r = \frac{3}{8}(2r-h)$, where α = half the angle tended by the sector. ELLIPSOID. Choose 3 coordinate axes x, y, and z; let and c denote the semi-lengths of the corresponding axes of the ellipsoid. coordinates of the center of gravity of one octant of the solid are $\bar{x} = 3a \div$ $\bar{y} = 3b \div 8$, and $\bar{z} = 3c \div 8$.

MOMENTS OF INERTIA OF AREAS AND MASSES

41. Areas

oment of inertia of a plane area with respect to a given line is the sum of products obtained by multiplying each element of area by the square of its nce from the line. The moment is called polar if the axis is perpendicular e plane area. The common symbol for moment of inertia is I; and a cript denotes the axis to which it refers. Let I = the moment of inertia t any axis; A the area of the figure and r the distance of any element of from the given axis, then $I = \int r^2\,dA$. RADIUS OF GYRATION k, of any figure, is the square root of the moment of inertia divided by the area of igure, thus $k = \sqrt{\frac{I}{A}}$, or $I = Ak^2$. PARALLEL AXIS THEOREM. $I = \bar{I} + Ad^2$, hich $\bar{I}$ is the moment of inertia with respect to an axis through the centroid I is moment of inertia about a parallel axis at distance d.

roduct of inertia J, of an area with respect to a pair of rectangular axes, e sum of the products obtained by multiplying each element of area by coordinates. Thus $J_{xy} = \int xy\,dA$. Product of inertia may be positive, tive, or zero, depending on the distribution of the area with respect to the . Moment of inertia is always positive and never zero. PARALLEL AXIS REM. $J = \bar{J} + A\bar{x}\bar{y}$, in which $\bar{J}$ is product of inertia of area A with respect to a pair entroidal axes, J is the product of inertia respect to a set of parallel axes, and $\bar{x}$ and e the distances from the parallel axes to the roid of the area. For a rectangle, $J_{xy} = A^2 +$ or a triangle, $J_{xy} = A^2 + 8$ (Fig 123). J is for an axis of symmetry and any line perlicular to that axis. The customary unit for both moment and product of ia is biquadratic inches = in^4. The principal axes of inertia at a point are e about which the moments of inertia are the greatest and the least; these will always be rectangular and the product of inertia for them is zero.

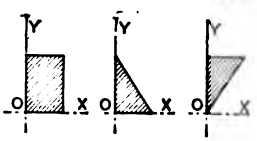

Fig 123

42. Oblique Axes and Least Radius of Gyration

blique axes. Let I_x, I_y, and J_{xy} represent moments and products of inertia a pair of rectangular axes at a point of an area, I_u the moment of inertia for any oblique axis through that point and α its angle with the X axis; then, $I_u = I_x \cos^2\alpha + I_y \sin^2\alpha - J_{xy} \sin 2\alpha$. For principal axes, $\tan 2\alpha = 2J_{xy} + (I_y - I_x)$.

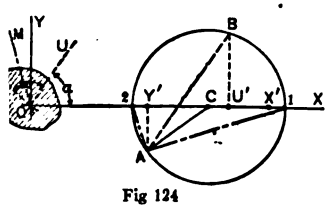

Fig 124

The equation for I_u is interpreted by the inertia circle as follows: Suppose I_x, I_y, and J_{xy} given for the shaded area in Fig 124. To convenient scale, plat OX' and OY' to esent I_x and I_y, and $Y'A$ to represent J_{xy} (downward if negative and up- l if positive). Center C is midway between X' and Y'. With CA a

radius, describe inertia circle. To find I_u, draw chord AB parallel to OU; draw perpendicular BU'. OU' (to scale) $= I_u$, and BU' (to scale) $= J_{uv}$. OM, parallel to A 2, is axis of least I; and a parallel to A 1, through is axis of greatest I. O 2 (to scale) is the value of least $I = I_2$; and O 1, v of greatest $I = I_1$. Least radius of gyration is measured perpendicular to OM and $= \sqrt{I_2 \div \text{area}}$. If principal moments of inertia (greatest and least a point are equal, ($I_1 = I_2$), then I for any oblique axis through the point same value; that is, $I_u = I_1 = I_2$.

44. Masses

Moment of inertia of a mass, with respect to an axis, is the algebraic s of the products of each element of mass and the square of its distance from t axis. $I = \Sigma mr^2$, in which m is any element of mass and r its distance from t axis. The common engineer's unit is slug-ft² (Art 53).

Radius of gyration is the distance from the axis to a point at wh the entire mass were concentrated, the moment of inertia would not be chan If k is the radius of gyration, and M the total mass, then $I = Mk^2$; or $k = \sqrt{I}$ and is measured in ft. Value of k is always between the least and gr values of r.

Parallel axis theorem. Let $\bar{I}$ be the moment of inertia with respect t axis through the center of gravity, and I the moment of inertia for any allel axis at a distance d; then $I = \bar{I} + Md^2$, and $k^2 = \bar{k}^2 + d^2$.

Principal axes and moments of inertia. The integrals $\int yz\,dm$, $\int zx$ and $\int xy\,dm$ are called products of inertia. For an oblique axis, through origin with direction angles, α, β, and γ,

$$I = I_x\cos^2\alpha + I_y\cos^2\beta + I_z\cos^2\gamma - 2J_{xy}\cos\alpha\cos\beta - 2J_{yz}\cos\beta\cos\gamma - 2J_{zx}\cos\gamma\cos\alpha$$

t each origin, there is one set of rectangular axes for which the three products of ia vanish, and with respect to two of which the moments of inertia are least and test of all moments of inertia with respect to axes at that origin. The axes are called cipal axes, and the moments of inertia with respect to them are called principal mo- ts of inertia. If a body has three planes of symmetry, at right angles to each other, lines of intersection are principal axes at the point of intersection. If a body has planes of symmetry, their intersection is a principal axis for every point on it as a, and the other two axes are in the planes of symmetry. If a body has one plane mmetry, any perpendicular to the plane is a principal axis at the point where the pierces the plane. At the origin, the x-axis is a principal axis if $J_{xy} = 0$ and $J_{xz} = 0$; -axis is a principal axis if $J_{xy} = 0$ and $J_y = 0$; and the z-axis is a principal axis if $= 0$ and $J_{yz} = 0$.

in circular lamina, of radius a and mass m, with respect to a diameter, $ma^2 + 4$. For axis perpendicular to face of lamina at its center, $I = ma^2 + 2$.

lid of revolution of volume V and mass M, with respect to its axis,

$$I = \left[\pi M \int y^4\,dx\right] \div 2\,V$$

respect to an axis at right angles to its geometrical axis,

$$I = \left[\pi M \int \left(\frac{y^4}{4} + x^2y^2\right)dx\right] \div V$$

in straight rod of length l and mass M. Axis perpendicular to rod at r, $I = Ml^2 \div 12$; at end, $I = Ml^2 \div 3$. Axis inclined to rod at angle α: ıter, $I = Ml^2 \sin^2\alpha \div 12$; at end, $I = Ml^2 \sin^2\alpha \div 3$.

ctangular prism of dimensions a, b, c. Axis through center of gravity, el to edge c, $I = M\,(a^2 + b^2) \div 12$. Axis through center of base bc and el to edge c, $I = M\,(4\,a^2 + b^2) \div 12$.

ht circular cylinder of length h and base radius a; for its geometrical $I = Ma^2 \div 2$. Axis through center of gravity, parallel to base, $I = M$ $+ h^2) \div 12$. Axis coinciding with diameter of base, $I = M\,(3\,a^2 + 4\,h^2) \div 12$.

llow circular cylinder of height h and radii R and r; about axis of cylin- $= M\,(R^2 + r^2) \div 2$. Axis through center of gravity, perpendicular to axis inder, $I = M\,(3\,R^2 + 3\,r^2 + h^2) \div 12$.

ptical cylinder, length h and semi-axes a and b; for its geometrical $I = M\,(a^2 + b^2) \div 4$. Axis through center of gravity, parallel to minor b, of elliptical section, $I = M\,(3\,a^2 + h^2) \div 12$.

ıere of radius a, about a diameter, $I = 2\,Ma^2 \div 5$.

ht circular cone, of height h and base radius a. About its axis, $I = 3\,Ma^2$ Axis through vertex, perpendicular to geometrical axis, $I = 3\,M\,(a^2 + 4\,h^2)$

psoid of axes $2\,a$, $2\,b$, and $2\,c$. About the axis $2\,b$, $I = M\,(a^2 + c^2) \div 5$.

ht rectangular pyramid, of height h and sides of base a and b, about **trical axis,** $I = M\,(a^2 + b^2) \div 20$. Axis through vertex perpendicular to **trical axis** and parallel to b side of base, $I = M\,(a^2 + 12\,h^2) \div 20$. Axis **h center** of gravity, parallel to b edge of base, $I = M\,(4\,a^2 + 3\,h^2) \div 80$.

:ular ring of circular section, radius of section $= r$, and center of **ı at distance** R from axis of ring. About axis of ring, $I = M\,(4\,R^2 + 3\,r^2)$ About **axis through center of gravity, perpendicular to axis** of ring, $(4\,R^2 + 5\,r^2) \div 8$.

KINEMATICS

46. Rectilinear Motion

A particle is in motion with respect to surrounding objects if its position w respect to them is continually changing. Displacement of a particle is its cha in position. If A is the position of a particle at a time t_1, and B its positio later time t_2, its displacement in the time interval $t_2 - t_1 = \Delta t$ is the vector $\overline{AB}$ matter whether path is straight or curved. Velocity of a particle is its time r of displacement. Acceleration of a particle is its time rate of change of velo

Rectilinear motion of a particle. Let s be distance measured along path of a particle, s_1 the distance from origin at time t_1, s_2 the distance later time t_2, $\Delta s = s_2 - s_1$ = displacement in time interval $\Delta t = t_2 - t_1$. T AVERAGE VELOCITY = $\Delta s \div \Delta t$. If the position changes at a uniform r actual velocity at any time = $\Delta s \div \Delta t$. For every case, INSTANTANEOUS VE ITY = $v = \dfrac{ds}{dt} = \text{limit}_{\Delta t \doteq 0} \left(\dfrac{\Delta s}{\Delta t}\right)$. UNIT OF VELOCITY is any distance unit divi by any time unit. SPEED is the name for magnitude of velocity, and d not refer to its sense or linear direction. If s is not known in terms of displacements for several time intervals, beginning or ending at the instant question, are known, an appr value of v can be obtained fro consideration of average spee

$s_2 - s_1 = \Delta s$, feet	Δt, seconds	$\Delta s \div \Delta t$, ft per sec
28.8 − 3.73 = 25.07	2 to 6 = 4	6.27
20.83 − 3.73 = 17.10	2 to 5 = 3	5.70
13.87 − 3.73 = 10.14	2 to 4 = 2	5.07
8.1 − 3.73 = 4.37	2 to 3 = 1	4.37

For example, determine the s at time $t = 2$ sec, having giv accompanying 4 sets of observa ues for Δs and Δt.

Column 3 is computed from the first two. As $\Delta t \doteq 0$, the value of aver velocity last column appears to approach a limit of 3.6 ft per sec. A value of this limit may determined graphically by platting time intervals along the horiz (Fig 138), and c sponding values of aver velocity vertically. The curve $ABCD$, "faired" to meet the ordinate through O at E (zero time interval), determines $v = OE = 3.6$ ft per sec.

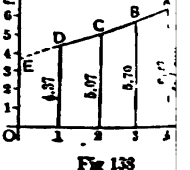

Fig 138

Let v_1 = velocity at time t_1, v_2 = velocity at a later time t_2, $\Delta v = v_2 - v_1$ = change in velocity in time interval Δt; then AVERAGE ACCELERATION = $\Delta v \div \Delta t$. If velocity changes at a uniform rate, the actual acceleration at any time $\Delta v \div \Delta t$. For every case, INSTANTANEOUS ACCELERATION

$$= a = \frac{dv}{dt} = \frac{d^2s}{dt^2} = \text{limit}_{\Delta t \doteq 0}\left(\frac{\Delta v}{\Delta t}\right)$$

UNIT OF ACCELERATION is any velocity unit divided by any time unit. unit used herein is feet per second per second, or ft per sec^2. If s or v are known in terms of t, but the placement or velocity record available, an approx value can be obtained from a consi tion of average accelerations the displacement record or available, values of v must first obtained as in the above numer example.

t, sec	v, ft per sec	Δt, sec	Δv, ft per sec	$\Delta v \div \Delta t$, ft per sec^2
2	3.6	2 to 6 = 4	4.8	1.2
3	5.1	2 to 5 = 3	3.9	1.3
4	6.4	2 to 4 = 2	2.8	1.4
5	7.5	2 to 3 = 1	1.5	1.5
6	8.4			

For example, determine the acceleration at time $t = 2$ sec, having given the five set values for t and v as shown in first two columns of accompanying table.

umns 3 and 4 are computed from the first two. s in last column are computed from third and fourth. = 0, the value of aver acceleration appears to ap- 1.6 ft per sec² as a limit. A value of this limit may ermined graphically by platting time intervals along orizontal (Fig 139), and corresponding values of aver ration vertically. The curve *ABCD*, "faired" to meet dinate through *O* at *E* (zero time interval), determines *E* = 1.6 ft per sec².

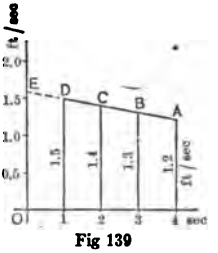

Fig 139

is given in terms of t, v and a are determined fferentiation as indicated above. If a is given ms of t, v and s are determined by integration. ormulas are

$$= \int_{t_1}^{t_2} a\,dt;\quad \int_{s_1}^{s_2} ds = \int_{t_1}^{t_2} v\,dt;\quad \int_{v_1}^{v_2} v\,dv = \int_{s_1}^{s_2} a\,ds;\quad \int_{t_1}^{t_2} dt = \int_{v_1}^{v_2} \frac{1}{a}\,dv = \int_{s_1}^{s_2} \frac{1}{v}\,ds$$

ich s_1, v_1, t_1, are simultaneous values. For uniform acceleration, a = con- $v = at + v_o$, $s = \frac{1}{2}at^2 + v_o t + s_o$, v_o being initial velocity and s_o initial dis- . For bodies falling from rest in vacuum, $v_o = 0$, $s_o = 0$, and $a = g =$ 32.2 ft per sec², $s = \frac{1}{2}gt^2$, $v = gt = \sqrt{2gs}$.

47. Motion Graphs

tion graphs. DISTANCE-TIME (*s-t*) GRAPH (Fig 140). Any ordinate ents value of s at corresponding time. Slope of tangent represents speed $= \frac{ds}{dt}$. CB must be read to distance scale and AB to time scale; then speed $v = CB \div AB$. SPEED-TIME (*v-t*) GRAPH (Fig 141). Any ordinate represents value of v at corresponding time. Slope of tangent represents $a = \frac{dv}{dt}$. FE is read to speed scale and DE to time scale; then $a = FE \div DE$. Area between curve and time axis, limited by any two ordinates, represents displacement in corresponding time interval. $\Delta s =$ of area × product of scale numbers = area × $m \times n$. If area is below axis it is considered minus. ACCELERATION-TIME (*a-t*) GRAPH. Any ordi-

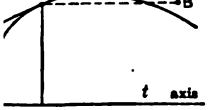

Fig 140

represents value at corresponding Area between and time axis, d by any two ites, represents e in speed in cor- ding time inter- Δv = sq in of area duct of scale numbers.

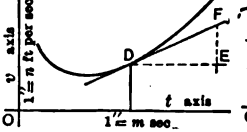

Fig 141

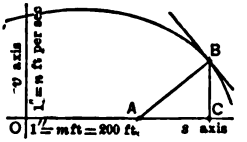

Fig 142

SPEED-DISTANCE (*v-s*) GRAPH (Fig 142), for recti- or curved path. The subnormal at any point B (line AC) represents ntial component of acceleration at corresponding instant. If m = distance number and n = speed scale number, then $a = AC$ (in) × $m^2 \div n$. (In Fig $m = 200$, $n = 30$.)

ple harmonic motion. If a point P moves in a circular path of radius r at uni- peed, its projection on any diameter has simple harmonic motion. Radius r is called

AMPLITUDE. PERIOD is time required for the projection to go from one end of diam to other and back. FREQUENCY is number of periods per unit time.

When $t = 0$, let P be at P_0 (Fig 143). ϵ is called the lead angle (lag, if negative). simple harmonic motion (S H M) of V in the vertical diam, $y = r \sin(\theta + \epsilon) = r \sin(\omega t +$ in which $\omega = \frac{d\theta}{dt}$ = radians per unit time.

$$v_y = r\omega \cos(\theta + \epsilon) = r\omega \cos(\omega t + \epsilon) = \omega x$$
$$a_y = -r\omega^2 \sin(\theta + \epsilon) = -r\omega^2 \sin(\omega t + \epsilon) = -\omega^2 y$$

For S H M of H in horiz diam:

$$x = r \cos(\theta + \epsilon) = r \cos(\omega t + \epsilon); \qquad v_x = -r\omega \sin(\theta + \epsilon) = -r\omega \sin(\omega t + \epsilon) =$$
$$a_x = -r\omega^2 \cos(\theta + \epsilon) = -r\omega^2 \cos(\omega t + \epsilon) = -\omega^2 x$$

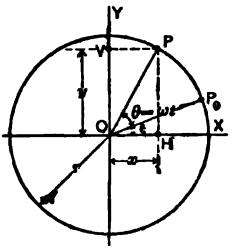

Fig 143

Crank and connecting-rod mechani Problem is to find expressions for the ve and acceleration of any point in the cross as A in Fig 144. Let $c = r \div l$, n = rev per (assumed constant), ω = radians of angle

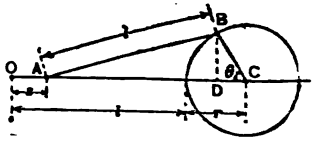

Fig 144

scribed by crank per second, and s = distance of A from its extreme left p tion, all distances expressed in ft. Then,

$$s = (l + r) - l(1 - c^2 \sin^2\theta)^{\frac{1}{2}} - r\cos\theta$$

$$v = r\omega\left(\sin\theta + \frac{c \sin 2\theta}{2(1 - c^2\sin^2\theta)^{\frac{1}{2}}}\right); \qquad a = r\omega^2\left(\cos\theta + \frac{c\cos 2\theta + c^2\sin^4\theta}{(1 - c^2\sin^2\theta)^{\frac{3}{2}}}\right.$$

The above formulas are exact; close approximations are:

$$s = r(1 - \cos\theta) + \tfrac{1}{4}cr(1 - \cos 2\theta); \qquad v = r\omega(\sin\theta + \tfrac{1}{2}c\sin 2\theta)$$
$$a = r\omega^2(\cos\theta + c\cos 2\theta)$$

Exact and approximate formulas for a give same values for extreme r and left positions of point A.

48. Curvilinear Motion

Curvilinear motion of a particle. The definitions of displacement velocity, given at the beginning of this article, apply to curvilinear mo Velocity is a vector quantity. If s is distance measured along the curved p the magnitude of velocity (speed) at an instant $= \frac{ds}{dt}$; the linear direct the velocity is tangent to the path at the instantaneous position of the par and the sense of velocity corresponds to the direction of motion of the par at the instant.

Acceleration for curvilinear motion is time rate of change of velocity a vector quantity. The velocity vector changes in magnitude and dir In Fig 145, let A, B, C represent positions of particle P in its curved p s, distance along the path, and v_1, v_2, v_3, velocity vectors at A, B, C. Plot v ity vectors $O'A'$, $O'B'$, $O'C'$, etc, from any origin O' to represent the velo

, *B*, *C*, etc. The curve $A'B'C'$, drawn through the ends of the vectors, is l a hodograph for the motion. For every position of *P* in its path, there corresponding position P' in odograph; and P' describes ce s' on hodograph, while scribes distance s on path. r $O'P'$ represents the velocity

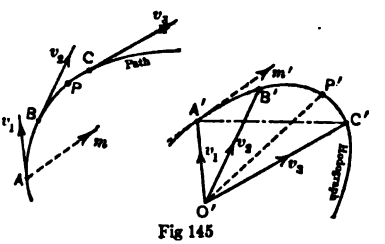

Fig 145

In time Δt, *P* moves from *C*, its velocity changes from to $O'C'$, and the velocity te is $A'C'$. AVERAGE ACRATION for interval Δt = or $A'C' \div \Delta t$), and it has irection of the chord $A'C'$. NTANEOUS ACCELERATION of *P* at $A = a$ = limit of aver acceleration as proaches zero.

$$a = \lim_{\Delta t \doteq 0}\left(\frac{\text{vector } A'C'}{\Delta t}\right) = \lim_{\Delta t \doteq 0}\left(\frac{\text{arc } A'B'C'}{\Delta t}\right) = \frac{ds'}{dt} = \text{speed of } P'$$

idograph. The direction of a is along the tangent $A'm'$, and as P' is movlockwise, the sense is as indicated by arrow at m'. Hence acceleration is Am, parallel to $A'M'$ and $= \frac{ds'}{dt}$. Unit is any velocity unit divided by ime unit.

otion graphs. Speed may be computed from a distance-time graph in ame way as for rectilinear motion. Tangential component (see Art 49) celeration may be computed from the speed-time graph; and the distance ay be obtained from the area under the curve.

49. Components of Velocity and Acceleration

mponents of velocity and acceleration of a particle for any curved (not a plane curve). The position of the particle *P*, being defined by its coates x, y, z, the axial components of velocity are $v_x = \frac{dx}{dt}$, $v_y = \frac{dy}{dt}$, $v_z = \frac{dz}{dt}$.

ltant velocity $v = \sqrt{v_x^2 + v_y^2 + v_z^2}$, and its direction cosines are $\cos\theta_x = \frac{v_x}{v}$, $_y = \frac{v_y}{v}$, $\cos\theta_z = \frac{v_z}{v}$. Axial components of acceleration are:

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}; \qquad a_y = \frac{dv_y}{dt} = \frac{d^2y}{dt^2}; \qquad a_z = \frac{dv_z}{dt} = \frac{d^2z}{dt^2}.$$

ltant acceleration $a = \sqrt{a_x^2 + a_y^2 + a_z^2}$; and its direction cosines are:

$$\cos\phi_x = \frac{a_x}{a}; \qquad \cos\phi_y = \frac{a_y}{a}; \qquad \cos\phi_z = \frac{a_z}{a}$$

e path is a plane curve, $v_z = 0$, $a_z = 0$. The tangential and normal comnts of acceleration are $a_t = \frac{dv}{dt} = \frac{d^2s}{dt^2}$, and $a_n = \frac{v^2}{\rho}$, ρ being the radius of ature. Resultant acceleration is $a = \sqrt{a_t^2 + a_n^2} = \sqrt{a_x^2 + a_y^2}$.

50. Translation

anslation of a rigid body is a motion such that each straight line in it ins fixed in direction. The paths of all particles of the body are exa

alike, straight or curved (not necessarily plane curves); the velocities of particles at an instant are the same, and their accelerations at an instant the same. For these reasons, it is customary to use the expressions, "velo of the body" and "acceleration of the body."

51. Rotation

Rotation of a rigid body is a motion such that one line of the body, or its extension, remains fixed. The fixed line is the axis. The plane that the mass center perpendicular to the axis is the plane of rotation. The pa

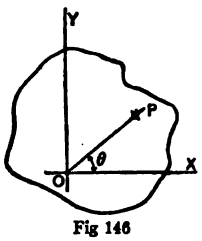

Fig 146

of all particles are circles with centers on the a Since all lines of the body parallel to the plane rotation sweep out equal angles in equal times, it customary to describe rotation by the behavior of radial line. In Fig 146 let θ be the angle from the axis to the radial line OP. $\Delta\theta = \theta_2 - \theta_1$ is the ANGU DISPLACEMENT of the body in the time $\Delta t = t_2 - t_1$. is expressed in any angular unit. ANGULAR VELO is the time rate of angular displacement. Aver angular velocity $= \dfrac{\theta_2 - \theta_1}{t_2 - t_1} = \dfrac{\Delta\theta}{\Delta t}$. The limit of average, as Δt approaches zero, is the instantan angular velocity. The symbol for angular velocity is ω, and $\omega = \lim_{\Delta t \to 0}\left(\frac{\Delta}{\Delta}\right.$ $= \dfrac{d\theta}{dt}$. The unit is any angular unit divided by any time unit, such as rad per sec, radians per min, rev per sec, or rev per min. The sign depends on numerator of the fraction, or the way in which θ is changing. ANGU ACCELERATION is the time rate of angular velocity. Average angular accele tion $= \dfrac{\omega_2 - \omega_1}{t_2 - t_1} = \dfrac{\Delta\omega}{\Delta t}$. The limit of this average, as Δt approaches zero instantaneous angular acceleration. The symbol for angular acceleration α, and $\alpha = \lim_{\Delta t \to 0}\left(\dfrac{\Delta\omega}{\Delta t}\right) = \dfrac{d\omega}{dt} = \dfrac{d^2\theta}{dt^2}$. The sign of α depends on the numera of the fraction, or on the way in which ω is changing.

Relations between v and a of any point P, of a rotating body and ω and α the body. Let r = radius of path of P. Then

$$v = r\omega, \qquad a_t = r\alpha, \qquad a_n = r\omega^2, \qquad a = r\sqrt{\alpha^2 + \omega^4}$$

Sense of v must agree with sense of ω. Sense of a_t must agree with se of α. Sense of a_n is always toward the axis.

52. Plane Motion

Plane motion of a rigid body is a motion such that each particle of body moves in a plane at a constant distance from a fixed plane, through center of gravity, called the plane of motion. Each line of the body paralle plane of motion turns through the same angle θ in the same time inter ANGULAR DISPLACEMENT of the body in time interval Δt is change of ang position of any line in the plane of motion. ANGULAR VELOCITY is time-rat angular displacement. ANGULAR ACCELERATION is time-rate of angular ve ity. The expressions, units, and rules of signs for plane motion are the s as those for rotation about a fixed axis (Art 51). Angular displacem $\Delta\theta = \theta_2 - \theta_1$; angular velocity is $\omega = \dfrac{d\theta}{dt}$; angular acceleration is $\alpha = \dfrac{d\omega}{dt} =$

lane motion may be traced by giving the history of the movement of one point of dy (called a base point) in its own curved path, and a description of the rotation of dy about the selected base point. The point selected e should be one for which the motion is readily spe-

In the case of a wheel rolling along a straight path, ater would be selected as a base point. VELOCITY r POINT P of the body, at an instant, with respect xed point O, is the vector sum of the velocity of oint A, with respect to O, and of velocity of P with to A due to rotation about A. Thus (Fig 147) O d point, A the moving base point, and P any other of the body at distance r from A; v_1 is velocity of A spect to O, and $v_2 = r\omega$ is velocity of P with respect to A. Resultant velocity of P spect to $O = v$; or

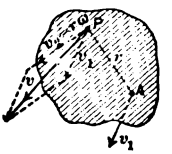

Fig 147

$$v_{P \text{ to } O} = v_{P \text{ to } A} + v_{A \text{ to } O}$$

ERATION OF ANY POINT P, with respect to a fixed point O, at an instant, has two ents; one is that of the base point A with respect to O, and the other that of P spect to base A. Acceleration of P with respect to A is rotational, and is con-tly replaced by its tangential and normal components, $a_t = r\alpha$ and $a_n = r\omega^2$. Then ant acceleration of P, with respect to O, is the vector sum of $r\alpha$, $r\omega^2$, and accel-n of A with respect to O. Thus (Fig 148) a_1 is acceleration of A to O, and accele-of P to A is resultant of a_t and a_n. Acceleration of P to O is a = vector sum of and a_n.

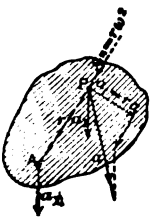

Fig 148

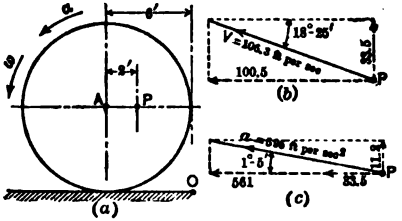

Fig 149

mple. A wheel of 6 ft radius rolls along a straight horiz path, and at a certain t the point P, 2 ft from center of wheel, is in the position shown in Fig 149a. At stant $\omega = 16.75$ radians per sec and $\alpha = 5.6$ radians per sec^2. Determine the y and acceleration of point P with respect to fixed point O at the specified instant. ION. Select center A as base point. From relation between v and a of any of a rotating body, and ω and α of the body (Art 51),

$v_A = r\omega = 2 \times 16.75 = 33.5$ ft per sec, vertically upward.

$v_O = r\omega = 6 \times 16.75 = 100.5$ ft per sec, horizontally toward left.

refore, $v_{P \text{ to } O} = 106.3$ ft per sec, upward to left, at 18° 25′ to horizontal (Fig 149b).

$a_{PO} = r\alpha = 6 \times 5.6 = 33.5$ ft per sec^2, horizontally toward left.

$= r\alpha = 2 \times 5.6 = 11.2$ ft per sec^2, vertically upward.

$= r\omega^2 = 2 \times (16.75)^2 = 561$ ft per sec^2, horizontally toward left.

refore, $a_{P \text{ to } O} = 595$ ft per sec^2, upward to left, at 1° 5′ to horizontal (Fig 149c).

tantaneous axis. For a body having plane motion, there is always one point in in its extension), at each instant, for which the velocity with respect to A is equal pposite to velocity of A with respect to O, that is, its velocity is zero at the instant. oint Q is called the INSTANTANEOUS (or instant) CENTER of rotation, and a line through pendicular to the plane of motion, is called the INSTANTANEOUS AXIS. Since Q is for the instant, the resultant velocities of all points at the instant are purely rota-about the instant axis. The instant center is the intersection of two lines drawn ny two points, C and D, in the plane of the motion, perpendicular to their ve

ties. If the velocity of the point C is known, ω for the body is determined by di v_C by the distance of C from Q, or by r_C. The velocity of any other point E is ω perpendicular to the radius r_E.

The position of Q in the body (or in its extension) is continually changing; its loc a line (usually curved) fixed in the body and moving with it, called the BODY CENTR The locus of the positions of Q in the fixed plane of motion is a line (usually curved) c the SPACE CENTRODE. The plane motion may be considered as produced by the rol without slipping, of the body centrode upon the space centrode.

KINETICS

53. Force and Mass Units

Mass is the quantity of matter in a body; it means substance as meas by a beam scale. Standards of mass are the pound and kilogram; they certain pieces of metal preserved in London and Paris respectively. mass of a body does not change with locality.

A force F acting on a particle of mass m gives it an acceleration a parallel to the f and the relation between the quantities is given by the equation $F = Kma$, in w K is a constant. It is customary to use a KINETIC SYSTEM OF UNITS, one for which K For such a system, unit force gives to unit mass unit acceleration. The $c\,g\,s$ syste units is a kinetic system; in it force is measured in dynes, mass in gm, and acce in cm per sec^2. The system is called an absolute system, because the units are

Units. The English speaking engineers' unit of force is the pull of the ea on 1 lb of mass. This amount of pull is called ONE POUND OF FORCE. A EARTH PULL varies with the elevation of the pound of mass, POUND FOR not an absolute unit. But, the range of variation is so slight, that the involved by assuming it constant is negligible in most computations engineers' corresponding mass unit has no standard name, but will here called a SLUG; it is the mass in which an acceleration of 1 ft per sec^2 is prod by a force of 1 lb. 1 slug of mass = about 32.2 lb of mass. In any comp tion that involves mass with pounds force, feet distance, and seconds time. should be reduced to slugs. Slugs of mass = wt of body (lb) ÷ 32.2 (ap value of acceleration due to gravity. In the following problems, the numer value of this acceleration is taken = 32).

54. Motion of Mass Center and Translation

For any particle of mass m

$$\sum \begin{pmatrix}\text{components in any } x \text{ direction of}\\ \text{all forces acting on the particle}\end{pmatrix} = \begin{pmatrix}\text{mass of particle times its } x \text{ comp}\\ \text{of acceleration}\end{pmatrix}$$

or, more briefly, if R_x represents the component of the resultant in the x direct

$$R_x = \Sigma F_x = ma_x$$

For any body, rigid or non-rigid,

$$\sum \begin{pmatrix}\text{components in any } x \text{ direction of}\\ \text{all external forces, pairs of in-}\\ \text{ternal forces excluded}\end{pmatrix} = \begin{pmatrix}\text{total mass of system times } x \text{ com}\\ \text{nent of acceleration of mass cent}\end{pmatrix}$$

or, more briefly, $$\Sigma F_x = M\bar{a}_x$$

This is known as the equation of the motion of the mass center of a ba system of bodies.

Rigid body having motion of translation. Velocities of all partic the same, and accelerations of all particles are the same. Resultant

d forces is a single force $R = Ma$, acting through the mass center, parallel acceleration,

$$\left(\begin{array}{l}\text{components in any } x \text{ direction of}\\ \text{applied forces including weight}\\ \text{of body}\end{array}\right) = \left(\begin{array}{l}\text{mass of body times the } x \text{ component of}\\ \text{acceleration}\end{array}\right)$$

ore briefly, $$R_x = \Sigma F_x = Ma_x \qquad (C)$$

$$\sum\left(\begin{array}{l}\text{moments about any } x\text{-axis of ap-}\\ \text{plied forces, including weight}\\ \text{of body}\end{array}\right) = \left(\begin{array}{l}\text{moment of resultant about same}\\ x\text{-axis}\end{array}\right)$$

$$\Sigma M_x = Ma_x \times arm \qquad (D)$$

lowing method of procedure is advisable in solving a problem: (*a*) Make tch of the body and place arrows upon it to represent all forces (including ant at mass center), indicating unknown forces or distances by letters. ume for each body if a system of bodies is under discussion. (*b*) Write as resolution equations (*C*) and moment equations (*D*) as there are unknown tities. (*c*) Solve the simultaneous equations to determine unknown quan-

ample 1. A rectangular box (Fig 150), 2 by 2 by 8 ft high, weighing 480 lb, is upon a rough flat-car. If the car is running on a straight level track, what acceleration will cause the box to tip? If coeff of friction = 0.22, will the box slip or tip first? SOLUTION. If tipping about edge O is impending, normal reaction is in position shown by N. By equation (*D*), $\Sigma M_O = -480 \times 1 = -\frac{480}{32} \times a \times 4$; hence $a = 8$ ft per sec². If slipping impends, N acts through some point O' at distance x from center line. $a_y = 0$; hence $\Sigma F_y = 0 = N - 480$, shows $N = 480$ lb. Limiting friction = 0.22 N = 105.6 lb. By equation (*C*), $\Sigma F_x = 105.6 = \frac{480}{32} \times a$; hence, $a = 7.04$ ft per sec² to cause slipping. As this value of a is smaller than the first one, slipping will occur before tipping. x may be found from $\Sigma M_{O'} = -4 \times Ma$.

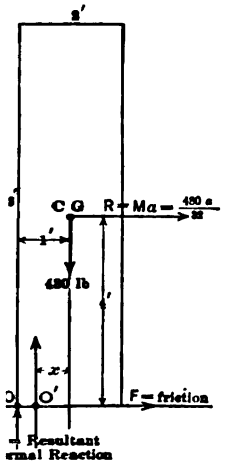

Fig 150

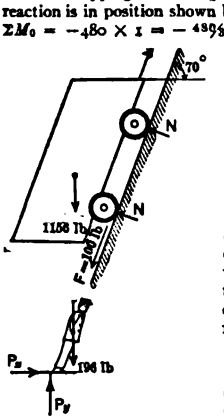

Fig 151

Example 2. A mine car (Fig 151), weighing 960 lb starts up a 70° slope, with an acceleration of 6 ft per sec², and is ed at top with an acceleration of 4 ft per sec². A 196-lb man stands in the car. mine starting and stopping tensions in the cable, if the frictional resistance amounts 100 lb parallel to track. Also find reaction of car on man's feet for starting and stop-

SOLUTION:

starting, man and car: $\Sigma F_x = T - 100 - 1156 \sin 70° = \frac{1156}{32} \times 6 = 216.9$; $T = 1402.9$ lb.

stopping, man and car: $\Sigma F_x = T - 100 - 1156 \sin 70° = \frac{1156}{32} \times (-4) = -144.5$; hence, $T = 1041.5$ lb.

n only, starting: $\Sigma F_x = P_x = \frac{196}{32} \times 6 \cos 70° = 12.57$ lb to right. $\Sigma F_y = P_y - 196 = \frac{196}{32} \times 6 \sin 70° = 34.55$ lb; hence, $P_y = 230.55$ lb up. $P = 231$ lb up to right, gle of 3° 7' to vertical.

Man only, stopping: $\Sigma F_x = -P_x = \frac{196}{32} \times (-4) \cos 70° = 8.38$ lb to left. ΣF
$+P_y - 196 = \frac{196}{32} \times (-4) \sin 70° = 23$ lb; hence, $P_y = 196 - 23 = 173$ lb up.
173.1 lb up to left, at angle of 2° 46′ to vertical.

55. Rotation and Plane Motion

Rigid body having motion of rotation about a fixed axis. Angular velo
$= \omega$, angular acceleration $= \alpha$, and moment of inertia of body about axi
rotation $= I$. The usual equation of motion is

$$\sum \begin{pmatrix} \text{moments about axis of rotation} \\ \text{of all external forces including} \\ \text{weight of body} \end{pmatrix} = \begin{pmatrix} \text{moment of inertia about axis of rota} \\ \text{tion times angular acceleration} \end{pmatrix}$$

or, more briefly,

$$\Sigma M = I\alpha$$

Equation (E) is used to determine one unknown quantity, as a force, arm, α, or I, according to the problem. In solving problems dealing wi

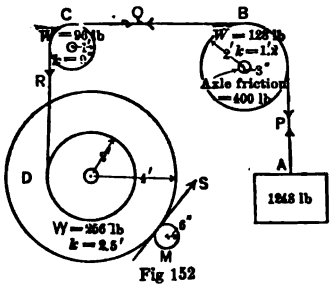

Fig 152

connected system, in which cer
bodies have motion of translation
others rotation, (C) and (E) may
used as simultaneous equations.

Example 3. Motor M (Fig 152) is ge
to hoisting drum D to raise and l
weight A. Assume A descending at s
of 15 ft per sec, and determine tange
force S, exerted by motor, that will st
in 30 ft at a uniform rate. Also, deter
tensions P, Q, and R during the mo
Neglect mass of motor armature, and ne
all friction except that of axle on B (s
and sizes are not selected to conform
practice, but to illustrate the metho
writing and using equations). SOLUTION. Determine acceleration of A by for
given under Rectilinear motion (Art 46).

$$\int_{v_1}^{v_2} v\,dv = \int_{s_1}^{s_2} a\,ds; \quad \left[\frac{v^2}{2}\right]_{15}^{0} = a\left[s\right]_{0}^{30}; \quad -\frac{(15)^2}{2} = a \times 30; \quad a = 3.75 \text{ ft per sec}^2 \text{ up}$$

By equations given under Angular acceleration (Art 51), $3.75 = a_A = 2a_B = a$
$2\alpha_D$. By (C) and (E) of this Art, equations of motion for each body are:

$$P - 1\,248 = \frac{1\,248}{32} \times 3.75 = 146.25$$

$$2 \times Q - 2 \times P + 400 \times \frac{1}{4} = \frac{128}{32}(1.2)^2 \times \frac{3.75}{2} = 10.8$$

$$1 \times R - 1 \times Q = \frac{96}{32}\left(\frac{3}{4}\right)^2 \times 3.75 = 6.33$$

$$4 \times S - 2 \times R = \frac{256}{32}\left(2.5\right)^2 \times \frac{3.75}{2} = 93.75$$

Solution of these simultaneous equations determines $S = 701.4$ lb, $P = 1\,354.1$
$Q = 1\,349.7$ lb and $R = 1\,356$ lb. The required motor torque is $S \times r = 701.4 \times$
$0.5 = 351$ ft-lb.

An axis of rotation which does not pass through the mass center must
held by forces (exerted by bearings) to keep it from shifting position. The
bearing reactions depend upon the weight of the body, the manner in wh
the mass of body is distributed about the axis, the applied forces, the angu
velocity ω, and the angular acceleration α. Generally, the resultant of
applied forces for such a body is not a single force, but a single force at a sele

a and a couple. Selecting the origin on the axis of rotation, the axial ponents of the single force and axial components of the couple are given by ollowing six equations:

$$\left.\begin{aligned} \Sigma F_x &= M\bar{x}\alpha - M\bar{x}\omega^2 & \Sigma M_x &= -\alpha\int xy\,dm - \omega^2\int yz\,dm \\ \Sigma F_y &= 0 & \Sigma M_y &= I_y\alpha \\ \Sigma F_z &= -M\bar{x}\alpha - M\bar{x}\omega^2 & \Sigma M_z &= -\alpha\int yz\,dm + \omega^2\int xy\,dm \end{aligned}\right\} \qquad (H)$$

ese equations, the axis of rotation is fundamentally the Y-axis; $\bar{x}$, $\bar{y}$, and the instantaneous coordinates of the mass center; ΣF_x, ΣF_y, ΣF_z are ums of components of all applied forces in the axial directions; ΣM_x, ΣM_z are the sums of moments of all applied forces about the axes; and onvention of signs for moments of forces, sense of α, and measurement of $= \frac{d^2\theta}{dt^2}$ is as follows:

rotation about Z-axis from $+X$ to $+Y$ is positive,
rotation about X-axis from $+Y$ to $+Z$ is positive,
rotation about Y-axis from $+Z$ to $+X$ is positive.

itions (H) are simultaneous at each instant. They are used more often termine the forces exerted by the bearings on the axle, than to determine esultant.

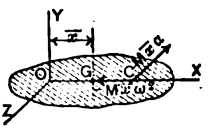

Fig 153

ecial Case (Fig 153). Choose the X-axis through the center and let XZ be a plane of symmetry of a geneous body. The resultant is a single force in the of symmetry having the Z component $-M\bar{x}\alpha$ and component $-M\bar{x}\omega^2$ acting at point C. $\overline{OC} = \frac{k^2_y}{\bar{x}}$, ing radius of gyration about Y-axis. If $\bar{x} = 0$, the result- ecomes a couple, in the XZ-plane, of moment $= \Sigma M_y = I_y\alpha$. If $\alpha = 0$ and $\bar{x} \neq 0$, sultant $= -M\bar{x}\omega^2$, in the sense CO. If $\alpha = 0$ and $\bar{x} = 0$, the resultant vanishes.

entrifugal force, body rotating about fixed Y-axis. Any particle of mass oves in a circular path of radius r. The resultant of all forces acting ne particle has a normal component $= mr\omega^2$ and a tangential component $r\alpha$. The component $mr\alpha$ increases or decreases the speed of the particle; component $mr\omega^2$ continually changes the direction of the linear velocity. resultant of such forces for all the particles of the body is equivalent to esultant specified by equations (H). If ω is constant and $\alpha = 0$, the re- nt force acting on a particle to make it rotate in its circular path is $mr\omega^2$ rd the axis, and is called CENTRIPETAL FORCE. CENTRIFUGAL FORCE for the cle is equal and opposite to centripetal force, and is exerted by the particle upon its neighboring particles, or upon the axis of rotation. CENTRIFUGAL RESULTANT for a body is the resultant of centrifugal forces of all its particles. Generally, this resultant is not a single force; it may be computed from equations (H) by making $\alpha = 0$ and reversing senses of resultant force and couple.

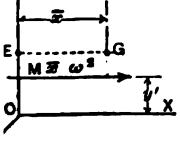

Fig 154

In the three following cases the centrifugal resultant is a single force: Case (*a*) Fig 154. Body has a plane of symmetry, XY, containing axis of rotation and mass center. Centrifugal resultant is a single force $= M\bar{x}\omega^2$, in XY plane, perpendicular to Y-axis, at a distance $\bar{y}' = \frac{\int xy\,dm}{M\bar{x}}$ from the XZ plane, and having sense EG. Case (*b*). Body has an axis of symmetry parallel to axis of rotation. Case (*c*). Body has plane of symmetry

perpendicular to axis of rotation. In cases (*b*) and (*c*), centrifugal resultant is a ... force = $M\bar{x}\omega^2$, acting through mass center outward and perpendicular to axis ... tion ($\bar{x}$ specified in Fig 154).

Center of percussion. Let Fig 155 represent a prismatic bar suspended on a h... zontal *Y*-axis at *O*. *G* is the mass center. If a force *P*, parallel to *X*-axis, is app... the body, the axle reaction at *OD* will generally be inclined t... *Z*-axis at some angle $\pm\beta$, the angle depending on the distance ... from the axis of rotation. If $k = k_z^2 \div \bar{x}$, in which k_z is rad... gyration about *Z*-axis, *P* will cause no *x* component of axle re... that is β will be zero, and the point *C*, where the action line ... intersects *OG*, is the center of percussion. In impact testing ... chines, heavy pendulums are used to deliver blows, and pr... design requires the striking point to coincide with the cent... percussion, in order to avoid shock to the axle and detrim... vibration of the pendulum itself.

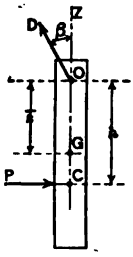

Fig 155

Body having plane motion. This motion has been ... scribed as translation of a base point in the plane of m... and rotation about the base point (Art 52). Choose ... mass center as base point and origin of coordinates ... the *XY* plane as plane of motion. Resultant of all ap... forces may be described as a single force and a couple in the plane of m... The couple is computed from the equation $\Sigma M_z = I_z\alpha = Mk_z^2\alpha$, in which Σ ... represents sum of moments of applied forces about *Z*-axis. I_z and k_z ... moment of inertia and radius of gyration about the *Z*-axis. The single ... acts through the mass center, and its components are given by $R_x = \Sigma F_x = M\bar{a}_x$, $R_y = \Sigma F_y = M\bar{a}_y$, $R_z = \Sigma F_z = 0$. ΣF_x, ΣF_y, and ΣF_z, are sums of co... ponents of all applied forces, and $\bar{a}_x$, $\bar{a}_y$ are components of acceleration of m... center.

56. Work, Energy and Power

Work of a constant force is the product of the force and the effectiv... placement of its application point. Effective displacement of applica... point is the component of the displacement parallel to the force. In Fig 156, the work of force *F* as application point describes path *AB* $= F \times AC$. Since $F\ (AB\cos\alpha) = (F\cos\alpha)\,AB$, the work is also equal to displacement of application point times component of force parallel to the displacement. Work of a variable force is $\int_{s_1}^{s_2} F\cos\alpha\,ds = \int_{s_1}^{s_2} F_t\,ds$, in which *F* is the variable force, *ds* is the elementary length of path, α is angle between force and element *ds*, and F_t is tangential component of *F*. The SIGN OF WORK is plus if force and effective displacement have same sense ... the sign is negative if they differ in sense.

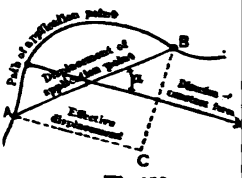

Fig 156

Unit of work is unit force times unit dist... 1 erg = 1 dyne cm. Work done by a body a... a force is equal and opposite to work d... the force on the body.

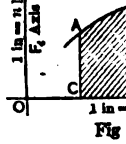

Fig 157

Work diagram (Fig 157). Plot values of F_t a... nates, corresponding values of *s* as abscissas dra... *AB* through ends of ordinates. Area *ABDC* t... equals work, in ft-lb, done by F_t over distance ...

Work of gravity on a body in any motion equals product of weight and ch... height of the center of gravity. Work of a central force *F* (one always directed t...

ed point), in any displacement of its application point, is $-\int_{r_1}^{r_2} F\,dr$, in which r_1 r_2 are the distances of the application point from the center at the beginning and of the displacement.

ork done by a pair of equal, opposite and colinear forces, for any motion of their cation points, A and B. If force on A acts from B toward A, work of the pair $\int_{r_1}^{r_2} F\,dr$; if force on A acts from A toward B, work of the pair $= -\int_{r_1}^{r_2} F\,dr$. In formulas, r_1 and r_2 are the initial and final distances between A and B. Work of a e T on a body for an angular displacement of θ radians $= T\theta$.

ower is time-rate of doing work. Let P = power and w = work; $w = \int_t ds$, and $P = \frac{dw}{dt} = F_t \frac{ds}{dt} = F_t v$, v being speed of application point of force

If P equals power (rate of doing work) of the steam in a locomotive, R = resistance (grade, air, rolling, etc), M, v, and a_t being mass, speed, and leration of train respectively, then $P = Rv + Mva_t$; $P = 0$, for $v = 0$. Power torque $T = T\omega$, ω being angular velocity of rotating body. UNIT of ER is any work unit divided by time unit, such as ft-lb per sec, ft-lb per or erg per sec. (10^7 ergs per sec = 1 watt). One horsepower = 550 ft-lb sec = 33 000 ft-lb per min.

nergy. A body possesses energy when it can do work against forces ap- to it. The amount of energy possessed at any instant is the amount of the body can do in changing to some standard state. KINETIC ENERGY E) of a body is energy possessed by virtue of its velocity, and the standard is zero velocity. K E of a particle is one half its mass times square of velocity. K E of a body in translation = $0.5\,Mv^2$. K E of a rotating $= 0.5\,I\omega^2 = 0.5\,Mk^2\omega^2$, I, k, and ω being moment of inertia, radius of tion, and angular velocity about axis of rotation. K E of a body having e motion = $0.5\,I\omega^2 = 0.5\,Mk^2\omega^2 = 0.5\,M\bar{v}^2 + 0.5\,\bar{I}\omega^2$, in which I and k refer stantaneous axis, $\bar{v}$ = velocity of mass center and $\bar{I}$ is moment of inertia t axis through mass center perpendicular to plane of motion. UNIT of K E me as unit of work, usually ft-lb. In computing K E, engineers use mass ugs, v in ft per sec, ω in radians per sec, and k in ft.

rinciple of work and kinetic energy. Total work of the applied forces ng on any body, or on any system of connected bodies, equals the change he kinetic energy of the body, or bodies. Work done = Δ K E. Change in gy in translation = $0.5\,M\,(v_2^2 - v_1^2)$, v_1 and v_2 being initial and final velocities. Change in energy in rotation = $0.5\,I\,(\omega_2^2 - \omega_1^2) = 0.5\,Mk^2\,(\omega_2^2 - \omega_1^2)$, ω_1 ω_2 being initial and final angular velocities. In plane motion, change in is

$$\Delta \text{ K E} = 0.5\,I\,(\omega_2^2 - \omega_1^2) = 0.5\,Mk^2\,(\omega_2^2 - \omega_1^2)$$
$$= 0.5\,M\,(\bar{v}_2^2 - \bar{v}_1^2) + 0.5\,\bar{I}\,(\omega_2^2 - \omega_1^2) = 0.5\,M(\bar{v}_2^2 - \bar{v}_1^2) + 0.5\,M\bar{k}^2\,(\omega_2^2 - \omega_1^2)$$

which I and k refer to instantaneous axis, $\bar{I}$ and $\bar{k}$ to a parallel axis through s center, and $\bar{v}$ is velocity of mass center.

xample. In example 3, Art 55 (Fig 152): (*a*) Use principle of work and K E to constant torque M necessary to stop body A in 30 ft, from a downward veloc of 1 per sec; (*b*) Find tension in cord P; (*c*) Find power of motor for above value of que, when veloc of A is 10 ft per sec. SOLUTION:

Work of gravity is positive = $1\,248 \times 30 = +37\,440$ ft-lb
Work of axle friction is negative = $-400 \times 3\frac{9}{2} \times \frac{1}{4} = -1\,500$ ft-lb
Work of motor is negative = $-M\theta = -M \times 60 \times 0.5 = -120\,M$ ft-lb
Total work = $-120\,M + 35\,940$
Final K E = 0, and change is a loss, or negative.

For D, $\Delta K E = \frac{1}{2} M k^2 (\omega_2^2 - \omega_1^2) = -\frac{1}{2} \times 285\frac{5}{32} \times 2\frac{3}{4} \times (13\frac{1}{2})^2 = -1\,308$ ft-lb
For C, $\Delta K E = \frac{1}{2} M k^2 (\omega_2^2 - \omega_1^2) = -\frac{1}{2} \times 9\frac{5}{32} \times 9\frac{1}{16} \times (15)^2 = -189.8$ ft-lb
For B, $\Delta K E = \frac{1}{2} M k^2 (\omega_2^2 - \omega_1^2) = -\frac{1}{2} \times 125\frac{5}{32} \times (1.2)^2 \times (13\frac{1}{2})^2 = -162$ ft-lb
For A, $\Delta K E = \frac{1}{2} M \quad (v_2^2 - v_1^2) = -\frac{1}{2} \times 124\frac{5}{32} \times (15)^2 = -4\,387.5$ ft-lb
Total $\Delta KE = -6\,147.3$ ft-lb

(*a*) Since $W = \Delta K E$, $\quad -120 M + 35\,940 = -6\,147.3$; **hence,** $M = 351$ ft-lb
(*b*) When $v_A = 10$ ft per sec, ω of motor $= 40$ radians per sec

Power = torque $\times \omega = 351 \times 40$ ft-lb per sec $= 351 \times 40 \div 550 = 25.5$ hp
(*c*) To find tension in P, apply principle of work and K E to body A alone.

Work $= (-P + 1\,280)\,30 = -30P + 37\,440$
$\Delta K E = \frac{1}{2} M (v_2^2 - v_1^2) = \frac{1}{2} 124\frac{5}{32} (0 - 15^2) = -4\,387.5$ ft-lb

Then, $\quad -30P + 37\,440 = -4\,387.5$; $\quad$ hence, $P = 1\,394.3$ lb

57. Impulse and Momentum

Linear impulse of a constant force F for time $t = F \times t$. If the force var in magnitude and direction, the impulse is computed from axial compone of impulse; and the axial components of impulse are found by taking the ti integrals of axial components of the force. The three axial component impul are $\int_{t_1}^{t_2} F_x\,dt$, $\int_{t_1}^{t_2} F_y\,dt$, $\int_{t_1}^{t_2} F_z\,dt$; the resultant of these is the impulse of t force F. Impulse is a vector quantity; hence the impulse of the force equ the square root of the sum of the squares of the components. The direct cosines of the resultant vector are determined in the usual manner (see resultan of noncoplanar concurrent forces or resultant velocity in curvilinear motio Unit of impulse is unit force times unit time, or lb-sec in engineers' units.

Angular impulse of a force about a line for a time interval dt is the prod of the moment of the force about the line and the time dt. If T represents t moment or torque of the force, the angular impulse for the time interval $t_2 - t_1$ $\int_{t_1}^{t_2} T\,dt$. Unit of angular impulse is unit moment times unit time, or ft-lb in engineers' units.

Sign of impulse. Impulse of a force tending to increase velocity of body to which the force is applied is positive; that which tends to decr velocity is negative.

Linear momentum of a particle is the product of its mass and velo It is a vector quantity and has the sense and direction of the velocity. U of momentum is unit mass times velocity and is equivalent to uni impulse. Linear momentum of a is the resultant, or vector sum, of momentums of its particles. In motion the linear momentum of a b is $M\bar{v}$, M being mass of the body $\bar{v}$ the velocity of its mass center engineers' units this is expressed in ft per sec or lb (force)-sec.

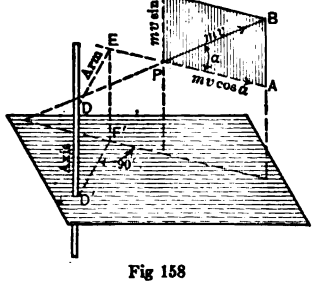

Fig 158

Angular momentum of a parti about an axis is the moment of its m mentum about that axis. In Fig 1 let mv = momentum of particle P solve the momentum into compon parallel and perpendicular to the axis. DE is perpendicular distance fro axis to line AP. The momentum of $P = mv \cos \alpha \times DE$. The angular m

tum of a body about an axis is the algebraic sum of the angular momen- of its particles. The angular momentum of a rotating body about the axis tation is $I\omega = Mk^2\omega$, I and k being moment of inertia and radius of gyration t the axis of rotation and ω the angular velocity. Engineers use I in slug in radians per sec, M in slugs and k in ft; the unit of the quantity is ft² per sec or lb (force)-ft-sec.

rinciple of impulse and momentum for a body. The change in the ponent of linear momentum parallel to any axis x in the time $t_2 - t_1$ equals algebraic sum of the components of the impulses of the applied forces par- to the axis in the same time, or, more briefly, $\Delta (M\bar{v}_x) = \sum \int_{t_1}^{t_2} F_x \, dt$. change in the angular momentum about any axis y in the time $t_2 - t_1$ equals algebraic sum of the angular impulses of the applied forces about the axis e same time, or, more briefly, $\Delta (I_y\omega) = \sum \int_{t_1}^{t_2} T_y \, dt$. This component of r momentum and the angular momentum remain constant if no forces are ied.

ample. In example 3, Art 55 (Fig 152), assume the time required to stop A is 4 sec. rinciple of impulse and momentum to determine tensions P and Q. SOLUTION:

r A, $$\Delta (M\bar{v}_x) = \sum \int_{t_1=0}^{t_2=4} F_x \, dt$$

$^{1249}/_{32}$ (0 − 15) = −585 = +1 248 × 4 − P × 4; hence, P = 1 394.3 lb

r B, $$\Delta (I_y\omega) = \sum \int_{t_1=0}^{t_2=4} T_y \, dt$$

$^{29}/_{32}$ (1.2)² (0 − 7.5) = −43.2 = −Q × 2 × 4 + 1 394.3 × 4 − 400 × $^{3}/_{32}$ × 4;

Q = 1 349.7 lb

CARBON, silicon
BORON
ALKALIES: lithium, sodium, potassium (ammonium, NH_4)
ALKALINE EARTHS: barium, strontium, calcium
MAGNESIUM, glucinum, zinc, cadmium, mercury
SILVER, copper, gold
ALUMINUM, yttrium, lanthanum, ytterbium, thallium
IRON, nickel, cobalt
MANGANESE
CHROMIUM, molybdenum, tungsten, uranium
TIN, lead, titanium, zirconium, cerium, thorium
VANADIUM, tantalum
PLATINUM, palladium, osmium, iridium

compute percentage composition from a formula. Two examples:

CALCIUM PHOSPHATE $Ca_3(PO_4)_2$

..	3×40.07	$= 120.21 =$	38.7%
..	2×31.04	$= 62.08 =$	20.0
..	$2 \times 4 \times 16$	$= 128.00 =$	41.3
ula-weight,		$= 310.29 =$	100.0

KAOLIN $H_2Al_2(SiO_4)_2, H_2O$

H.....	2×1.008	$= 2.016 =$	0.8%
Al.....	2×27.1	$= 54.2 =$	20.9
Si.....	2×28.3	$= 56.6 =$	21.8
O.....	$2 \times 4 \times 16$	$= 128.0 =$	49.5
H_2O	$2.016 + 16$	$= 18.016 =$	7.0
Formula-weight		$= 258.832 =$	100.0

letermine formula from analysis: divide percentage of each element by nic weight, and reduce quotients to least common denominator. Example:

Phosphorus.....	21.82% ÷ 31.04 = 0.703 = 1	$= Na_2HPO_4$
Hydrogen.....	0.71% ÷ 1.01 = 0.703 = 1	
Sodium.....	32.43% ÷ 23.00 = 1.407 = 2	
Oxygen.....	45.02% ÷ 16.00 = 2.814 = 4	
	99.98%	

putations from analysis will not always work out with mathematical preci- it small errors can be compensated according to the fundamental law that ts always combine in simple proportions represented by whole numbers.

rmining formula of a mineral from its analysis is complicated by st few natural substances are "chemically pure"; certain constituents neral from one locality may be found, in same mineral from a different , to be replaced wholly or partly by another element. First convert age of minor element to equivalent percentage of preponderating element group, equivalents being directly proportional to atomic weights; then e ratio of elements (or molecules) in same manner as above. Example:

sis of a garnet:

.....	39.85%
O_3.....	22.07
O_3.....	1.13
O.....	0.68
).....	36.31
	100.04

$Fe_2O_3 : Al_2O_3 = (2 \times 55.84 + 3 \times 16 = 159.68) : (2 \times 27.1 + 3 \times 16 = 102.2) = 1.13 : x$. $x = 0.72$; that is, 1.13% of Fe_2O_3 is equivalent to 0.72% of Al_2O_3. Similarly, $MgO : CaO = (24.32 + 16 = 40.32) : (40.07 + 16 = 56.07) = 0.68 : x$. $x = 0.94\%$ CaO.

SiO_2.....	$39.85 + (28.3 + 32)$	$= 0.660 = 3$
Al_2O_3.....	$(22.07 + 0.72) \div 102.2$	$= 0.223 = 1$
CaO.....	$(36.31 + 0.94) \div 56.07$	$= 0.664 = 3$

Type formula: $3\,CaO \cdot Al_2O_3 \cdot 3\,SiO_2$

Table 2. Composition, etc, of More Important Industrial Compounds

(For composition of minerals, see Sec 1, Tables I–VIII; and Sec 28, Table 1 gases, see Sec 14, Table 4. For additional organic and inorganic compounds, see Nostrand's "Chemical Annual," Merck's "Index," or U S Pharmacopoeia).

Name	Formula	Mol wt	Sp gr

1. Definitions

dromechanics deals with the mechanics of fluids. Fluids embrace LIQUIDS ically incompressible, and the molecules of which are not fixed in position) ASES (compressible and expand spontaneously, volume depends on press mp, and molecules are free). Hydromechanics comprises HYDROSTATICS, g with fluids at rest and HYDRODYNAMICS, with fluids in motion. HY- ics treats of the hydrostatics and hydrodynamics of water, but the term n restricted to hydrodynamics only, or the mechanics of water in motion.

principles and formulas applying to water apply also to other liquids, but are ed by VISCOSITY, or internal friction. This is absent in a perfect liquid, but is t to some extent in water and to a large extent in viscous liquids like syrups, in which article requires a shearing force to move it over adjacent particles. It is important hydrodynamics.

w of the principles of hydrostatics were established by Archimedes (250 B C), other [illegible] (1640), Torricelli and Pascal (1650). Hydrodynamics is a very modern

iency $= \left(1 - 4\mu\frac{C}{D}\right) \div \left(1 + 4\mu\frac{c}{d}\right)$. μ is variable, but may be taken at 0.12 to r well-oiled packing.

4. Pressure Produced by Gravity

sidering a liquid divided into layers, the press in each layer is: (*a*) pro- nal to its depth, (*b*) proportional to wt of the liquid, (*c*) the same at all in each layer, (*d*) same in all directions at any depth, (*e*) independent of id shape of containing vessel. Also water surface is normal to the result- the forces acting.

s (*a*) and (*b*), above, are practically self-evident. $P = wAh$, where P = total press, = wt of 1 cu ft of water, lb; A = area, sq ft; h = head, ft. If $p = P \div A$ =

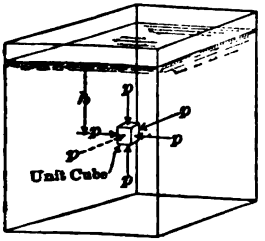

Fig 2

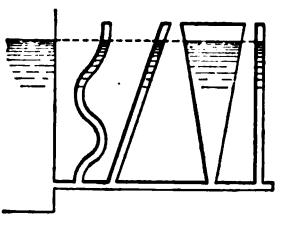

Fig 3

ess, then p in lb per sq ft $= wh = 62.5\,h$, or in lb per sq in $= 0.434\,h$, or h in ft = oes p in lb per sq in. (*c*) and (*d*) follow from Pascal's law (see Fig 2). (*e*) is shown 3, where the bottoms of vessels are at same level, and unit pressures must be same would take place.

5. Total Normal Pressure and Center of Pressure

al normal press, or press acting at right angles to surface $= P_n = wAh_{cg}$; × **area** of surface × distance of center of gravity of the surface below water This applies to any surface plane, curved or 1. Thus the total normal press against the ace of dam shown in Fig 5*a* is $P_n = 62.5 \times h \div 2) = \frac{1}{2}\,wh^2$ lb per lin ft.

al pressure in any direction $= P' = P_n \cos\theta$ h_{cg}, where θ = angle between normal and the lirection. That is, the total press in any direc- total normal press on a projection ($= A'$) per- ular to that direction. In Fig 5*d*, total horiz , $P_h = wh^2 \div 2$, the same as the normal press t a vertical projection (Fig 5*a*).

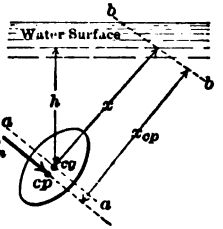

Fig 4

ter of pressure (*cp*) of a submerged surface is the point of application resultant press. For a submerged rectangle the center of press is $\frac{2}{3}\,h$ the water surface, when the top of the rectangle is at the surface (Fig 5*a*) eral the distance $x_{cp} = I \div S$, where I is the moment of inertia of the

face and S its statical moment (= area × distance of cg from axis) both wit reference to an axis situated at intersection of the plane of the surface with th water level. x_{cp} is the perpendicular distance from this axis to the cp.

In applying this formula use is made of the well-known relation $I = I' + Ax^2$, whe I = moment of inertia about any axis, I' = that about an axis through cg of surfac

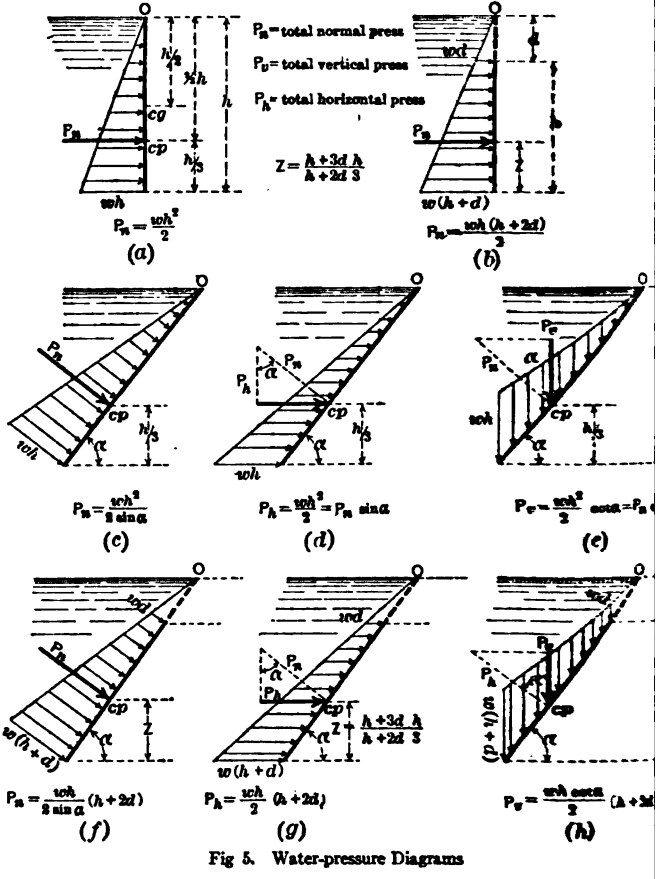

Fig 5. Water-pressure Diagrams

A = area of surface, and x = distance between axes. Thus for circular area of Fig 4 is axis through cg, bb is water surface axis, $A = \pi r^2$, $I' = \pi r^4 + 4$; hence, $x_{cp} = (\pi r^4 + \pi r^2 x^2) + \pi r^2 x = (r^2 + 4x) + x$, or when the circle is vertical $= (r^2 + 4h) + h$.

It is seen that the center of press is lower than the center of gravity, and that the tance between them decreases as the head increases. Practically they may be taken coincident, when the head exceeds 3 or 4 times the vertical dimension of the surface.

6. Pressure against Dams and Gates

ig 5 shows graphically the variation in normal, horiz, and vertical press, total
s and centers of press for rectangular surfaces of unit width. The press at
er surface is 0, and at depth $h = wh$ in all
ctions; hence the variation is uniform and
ltant press acts through the cg of the pres-
figure.

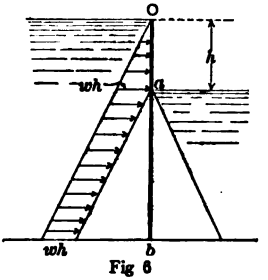

Fig 6

case of press from both sides (Fig 6), the resultant
, represented by arrows and found by drawing the
ss triangles, is uniform in intensity and = wh for
depth below the water surface a. It depends only
he difference in levels h. Thus a gate anywhere
ween a and b would be subjected to the same result-
ress, independent of its depth below a. The point
plication of the total resultant press against the
is best found by taking the difference in moments
e 2 press triangles about b.

7. Pressure in Pipes and Tanks

Hoop tension. Considering the vertical section of pipe in Fig 7*a* as a unit
1) in height, subjected to a uniform internal press of p lb per sq in, this press
luces tension in the pipe = T (Fig 7*b*), which tends to rupture the pipe longi-
tudinally. From the principle that the total
press in any direction = total normal press on a
projection perpendicular to that direction, $2T = pd$, or T (lb per lin in of pipe) = p (lb per sq in) $\times r$ (radius of pipe, in). If f = allowable stress in shell, lb per sq in, then required thickness t (in) = $pr \div f = 0.434\, hr \div f$, where h = head in ft.

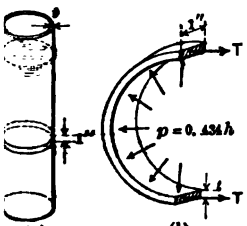

Fig 7. Pressure in Pipes and Tanks

Example. Head, 400 ft; diam, 3 ft; riveted steel pipe; joint efficiency, 70%; f = 14 000 lb per sq in. $t = 0.434 \times 400 \times 18 \div (14\,000 \times 0.70) = 0.32$, or $\frac{3}{8}$ in. This formula holds only for thin shells. The limit is usually put at $t = \frac{1}{20}\, d$. For thick shells, see *Proc* Am Soc Mech Engrs, 1912. Also the press p will only be uniform for a vertical pipe, but may be so
a for a small pipe under a large head. For large pipes, besides the allowance for
nal press, other factors must be taken into account (Art 13). Same principle is used
signing the hoops or bands for wood-stave pipes or water tanks, or for the reinforcing
in reinforced concrete tanks (Art 12).

Flotation and Loss of Weight in Water. (See Merriman, Treatise Hydraulics; also Sec 1, Art 3, and Sec 31, Art 5.)

HYDRODYNAMICS

9. Flow through Orifices and Nozzles

Torricelli's theorem (1644). The theoretical velocity of flow from an orifice is the
e as that acquired by a body falling freely through a height equal to the head of water
he orifice. That is, theoretically the velocity of flow in ft per sec from an orifice
$\sqrt{2gh}$, where g = acceleration of gravity, ft per sec per sec, and h = head on orifice, ft.
formula represents a theoretical limit which can not be exceeded by the actual velocity.

ig 8*a* shows the STANDARD OR SHARP-EDGED ORIFICE. The contracted vein,
ENA CONTRACTA, of a jet issuing from a standard orifice, is due to the fact
t the particles of water converge as they approach the orifice and
e for a short distance beyond it. The contracted section occurs at a

from the orifice of about 0.5 the diam of the orifice. Its diam is about 0.5 that of the orifice and its area about 0.62, this latter figure being the coeff contraction = c'. Experiments show that the average velocity at the contracted section is about 0.98 (= c_1 = coeff of velocity) times the theoretical velocity

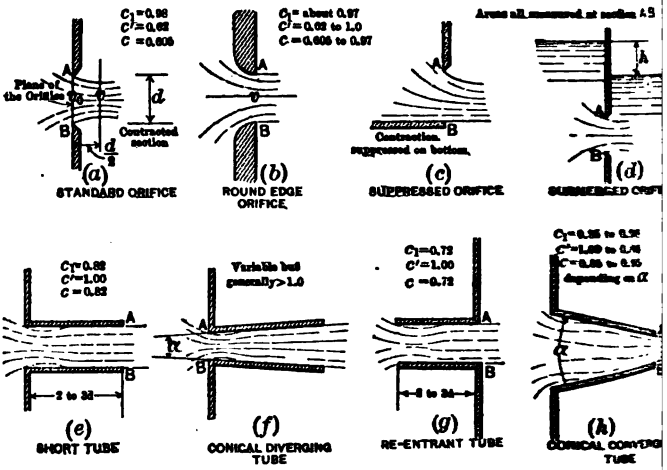

Fig 8. Orifices and Short Tubes

hence the velocity in ft per sec in the contracted section = $c_1\sqrt{2gh}$, the aver being $0.98\sqrt{2gh}$.

Since the discharge, in ft per sec, flowing from the orifice = Q = area × velocit the theoretical discharge = $av = a\sqrt{2gh}$, where a = area of orifice in sq Practically $Q = c'ac_1\sqrt{2gh} = ca\sqrt{2gh}$, where $c = c'c_1$ = COEFFICIENT OF DI CHARGE, the average value of which is 0.605. Theoretically the shape of or he on the orifice has no effect. But experiments show that c is greater for low hea than high, greater for rectangles than squares, and greater for squares th circles, and varies from 0.59 to 0.63 or more. Averages: for rectangular ori 0.604, for circular 0.597. For accurate work use the tabulated values given text books on Hydraulics. The preceding figures apply to the contracted s tion. A fundamental law of hydrodynamics, the EQUATION OF CONTINUIT is that for steady flow equal masses or weights of a fluid must pass all cr sections in equal times. This reduces to equal volumes for water, since it practically incompressible. Hence, the discharge in the plane of the orifice m equal that at the contracted section = $ca\sqrt{2gh}$, or since $v = Q \div a$, the velo in the plane of the orifice = $v_0 = ca\sqrt{2gh} \div a = c\sqrt{2gh} = c'v$.

In these formulas the HEAD ON THE ORIFICE should be taken as the head o center of press, but if the head is greater than 2 or 3 times the vertical dimensi of the orifice, the head on the center of gravity of the orifice may be used. F a circular orifice the head on the center of press = $(r^2 + 4h) \div h$, where r radius and h = head on cg. For rectangular orifices a convenient formula small heads is $Q = c\,\frac{2}{3}\,b\sqrt{2g}\left(h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}}\right)$, where b = breadth, h_2 = depth to bo tom and h_1 = depth to top of orifice. This allows for difference between cp and

oss of head in an orifice = $h' = (1 - c_1^2)\, h = (1 + c_1^2 - 1)\, v^2 \div 2g = (1 + c_1^2 - 1)\, v_0^2 \div 2g$. For a standard orifice, $c_1 = 0.98$, $c' = 0.62$ and $h' = 0.04$. $h = 0.041\, v^2 \div 2g = 0.11\, v_0^2 \div 2g$.

ound-edge orifices (Fig 8*b*). By rounding the inner edge of an orifice c' may have value between 0.62 and 1.0, depending on how closely the rounding corresponds to the our of the jet. An orifice for measuring discharge should not be round-edged, because ncertainty in its value of c, but the increase in Q due to rounding may often be taken ntage of. Aver value of c for round-edge orifice = 0.8.

uppression of contraction occurs when the orifice edges are nearer than 3 times the : dimension of the orifice from sides or bottom of tank. Preventing the jet from con- ting increases c' and hence the discharge. K (coeff of discharge for a suppressed ce) $= c\,(1 + 0.15\,n)$ for rectangular and $= c\,(1 + 0.13\,n)$ for circular orifice; where coeff for standard orifice with full contraction and nP = portion of perimeter having ontraction, P being the entire perimeter.

ubmerged orifices. EFFECTIVE HEAD is the difference in level between the 2 water ices, and the action of the orifice is independent of its depth below the lower water ice. c is slightly smaller than for free discharge into air and is usually taken as 0.60.

'elocity of approach. In above formulas h is taken as constant, but this occur only when the inflow Q is constant. The water then approaches the ice with an initial velocity, and the effective head is $H = h + h_v$, where $h_v = \div 2g$ and v_a = velocity of approach. For a standard orifice,

$$v = c_1 \sqrt{\frac{2gh}{1 - c^2(a/A)^2}} \text{ and } Q = a \sqrt{\frac{2gh}{(1/c)^2 - (a/A)^2}}$$

re a = area of orifice and A = that of tank. When $a \div A$ is 0.2 or less, the r due to neglecting v_a is negligible. In the case of water approaching a large ice in a canal or conduit, the formula for a rectangular orifice under small d is $Q = c\, \tfrac{2}{3}\, b \sqrt{2g}\, [(h_2 + h_v)^{3/2} - (h_1 + h_v)^{3/2}]$, which is the basis for the ncis weir formulas with v_a.

ime required to empty any vessel of uniform horiz cross-section is t (sec) $= 2A\,(\sqrt{H} - \sqrt{h}) \div [ca\sqrt{2g}]$, where A = cross-sectional area of vessel, a = ice area, and H = initial and h = final head on orifice.

low under pressure may be estimated by the same formulas given above, pressure being first reduced to equivalent head.

xample. Find Q when an orifice 3 in diameter is first opened in a tank containing 3 ft r with 50 lb per sq in gage air pressure on top. Effective head $= 3 + 50 \times 144 \div$ $= 118$ ft. $Q = 0.60 \times (0.785 \div 16) \times 8.02 \times \sqrt{118} = 2.52$ cu ft per sec.

or fluids other than water the corresponding wt per cu ft is used to determine the tive head, and c must also be modified. Thus, in preceding example, if the fluid is cury, $c = 0.62$ and wt = 850 lb per cu ft, or $h = 3 + 50 \times 144 \div 850 = 11.5$, and 0.80 cu ft sec. Same formula is used to find the discharge of air from an orifice, the f being about 0.60.

hort tubes are short sections of cylindrical or tapering pipe, used for connecting two els or other special purposes. Fig 8 shows some common forms, with their coeffs.

lozzles are of the smooth or ring type. The former is the commoner. The

harge is given by $q = 29.83\, D^2 \sqrt{\dfrac{p}{\left(\frac{1}{c}\right)^2 - \left(\frac{D}{d}\right)^4}}$, where q = discharge, gal per

, p = press at the nozzle, lb per sq in, c = coeff of discharge = c_1 for a smooth zle, since there is no contraction, and $c' = 1$. (For smooth nozzle, c

from 0.990 for a 1-in to 0.997 for a 6-in nozzle.) D = diam of nozzle, in, and diam of pipe. If q is required in cu ft per sec, use 0.0665 instead of 29.83. T formula allows for velocity of approach, which is sometimes considerable. I is measured by a Pitot gage held in the nozzle (Art 19), $q = 29.83\ cd^2\sqrt{p_1}$, wh p_1 = press recorded on gage in lb.

10. Flow Over Weirs and Dams

Contracted weir (Fig 9) with end contractions is a rectangular notch in upper edge of a vertical wall. The length of notch is less than that of the ch nel, and, that the end contracti be complete, there should be a di ance of not less than 3 H on the si and the crest should be at least from bottom of channel. If the is the full width of the channel traction is suppressed on the ends it is known as a SUPPRESSED WEIR ing no end contractions. There many weir formulas. The rational formula is $Q = c\ \frac{2}{3}\ b\sqrt{2g}\ H^{\frac{3}{2}}$, where a constant or coeff of discharge, b = breadth, and H = head in ft. It is deri from the orifice formula by letting the head on the top of the orifice = 0. Fra uses $Q = 3.33\ bH^{\frac{3}{2}}$ for a suppressed weir (Table 1), and for a contracted we

amples. (*a*) Suppressed weir, no velocity of approach, $b = 4$ ft, $H = 1.73$ ft. Find
From **Table I**, Q per ft of length $= 7.577$ and total $= 7.577 \times 4 = 30.31$ cu ft sec.
Contracted weir, same as above. Q per ft of length $= 7.577$, but effective length $- 0.2\ H = 4 - 0.35 = 3.65$ ft, and total $Q = 27.65$ cu ft per sec.
Contracted weir as above, with average velocity of approach of 2 ft per sec. From e 2, $h_v = 0.062$ and $1.73 + 1.5 \times 0.062 = 1.82$, which from Table 1 gives 8.176 in ft., or a total of $8.176 \times 3.65 = 29.80$ cu ft per sec.

obtain accurate results, the weir must be constructed in a standard manner, similar at used in obtaining the experimental coefficients: the notch must have sharp edges as standard orifice; crest must be level sides vertical; length should be between d $3\ H$; velocity of approach should be ! (area of cross-section of channel of ach should be at least $6\ bH$); sides crest should be $3\ H$ from sides and om of channel; head should be meas- accurately, 4 to 6 ft upstream, to elim- effect of slope in the water surface rd the weir (for common work a stake be driven in the bed of the channel of ach, Fig 10, and cut off level with the crest, H being obtained by measuring water level on a graduated rod held on this stake. For accurate work a hook gage ld be used); for suppressed weirs there must be free access of air to the under side e overflowing sheet of water or NAPPE.

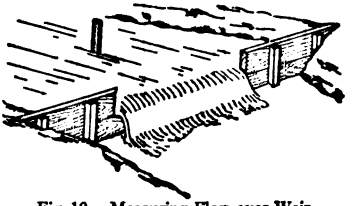

Fig 10. Measuring Flow over Weir

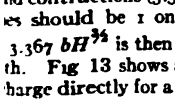
mple. Design a contracted weir to measure the flow of a stream 6 ft wide by 2 ft , the aver velocity of which, obtained roughly by a float, was 3 ft sec. Q = approx ft per sec. For a depth of 1 ft Q (Table 1) $= 3.33$ cu ft per sec per ft of length, and equired length would be $36 + 3.33$, or 11 ft, which is too long (see above). By further using Table 2, it is found that a weir 8 ft long, with $H = 1.25$ ft, will give the required atio about 1 : 6.4). Crest of the weir must be about 4 ft ($3\ H = 3.75$) above bottom tream and width of channel of approach at least 16 ft ($8 + 2 \times 3 \times 1.25 = 15.5$). e channel is narrower when flooded, it should be widened or a suppressed weir used.



11. Triangular Weir

Triangular weir (Fig 11) is convenient for small quantities of water. It should have sharp inner corners, sides of equal slope, and bottom angle should be a right angle. For this weir $Q = 2.53\ H^{5/2}$, H being measured from bottom of notch.

rapezoidal or Cippoletti weir (Fig 12) saves time in computations, as a e may be made or a stick graduated to read the discharge directly, as for rtangular suppressed weir. Sides are sloped to make the discharge through triangular end portions equal to the loss due nd contractions $(3.33 \times 0.2 \times H \times H^{3/2})$. End es should be 1 on 4, as shown. Formula $3.367\ bH^{3/2}$ is then used, b being the bottom th. Fig 13 shows a stick graduated to read harge directly for a trapezoidal weir 1 ft long 1).

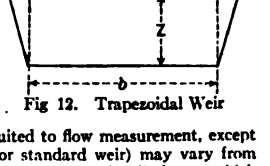


Fig 12. Trapezoidal Weir

pillway dams are a type of weir, but are seldom suited to flow measurement, except roximately, as the coeff in Francis formula (3.33 for standard weir) may vary from to 4.2. A sloping upstream face on the dam generally increases the discharge, which

is also modified by width and shape of crest and inclination of downstream face. In signing spillways, the flood flow Q is approximately known, the breadth b is usually by the flood width of channel below the dam, and the able flood height H over the spillway may be computed Francis formula. As it is difficult to determine the charge, an ample factor of safety is desirable, and the used should be small enough to be on safe side (3.3 is mon coeff for masonry spillways)

11. Flow in Pipes and Open Channels

Bernoulli (1738) stated the law of steady flow. "... any section of a tube or pipe, under steady flow with friction, the press head plus the velocity head is equal to the hydrostatic head that obtains when there is flow." This law, together with the equation of continuity (Art 9) and a formula for loss of head in friction is fundamental in determining flow conditions in pipes.

Loss of head by friction in pipes is inconsiderable in short tubes, and is provided for in the coeff of discharge; for long pipes it is important and as the length increases, assumes most of the available head. The proposed formulas for loss of head in friction are so numerous, and some so complicated, that the engineer may be at a loss which to use. All reduce practically to one of the two forms given below; their chief value is not in their form, but in the fact that coefficients have been determined from experiments on certain kinds of pipes with use of a particular form of formula, so that in designing a given pipe the equation for which the best coefficients are available should be used.

Experimental laws of friction head. The loss of head: (a) is directly proportional to the length l of the pipe; (b) is inversely proportional to the diam d; (c) increases nearly as the square of the velocity v; (d) increases with the roughness of the interior surface; and is independent of the pressure. These laws are expressed by $h_f = f \frac{l}{d} \cdot \frac{v^2}{2g}$, where $2g$ is introduced so that h_f is expressed in terms of velocity head, which is convenient. Experiments show that the loss is not exactly proportional to v^2. For low velocities the loss is due to shearing action and varies simply as v. When critical velocity is reached, beyond which the flow is not smooth but turbulent, the loss being of an impact as well as shearing nature, and the variation expressed by v^2 (approx). Reynolds gives for the critical velocity, $v = 0.0...$ where v = ft per sec and d = diam in ft. Since the loss is not accurately expressed by v^2 and the exponent of v should really vary, two types of formula have been developed: first, those which reduce to the above form, where v is squared and the variation is allowed for by making f vary with v and also with d as found in experiment; second, the so-called exponential formulas, in which f is constant and the exponents of v and d are varied to suit aver conditions.

Other losses occur, but can generally be disregarded. Thus the ENTRANCE LOSS = $m \frac{v^2}{2g}$, where $m = 1$ for an inward projecting pipe and 0.5 for a pipe set flush with reservoir or tank wall. CURVATURE also causes a loss, that is least for a 90° bend if radius is about $3d$. For a 90° bend in 6-in pipe, the loss is nearly equal to that in a length of straight pipe, and for 30-in pipe in a length of 40 ft. For intermediate sizes loss varies roughly with diam.

LOSS IN EXPANSION from a small pipe with velocity V_1 to large pipe with velocity V_2 is $(V_1 - V_2)^2 \div 2g$. LOSS IN CONTRACTION from large to small pipe may be taken

$+ 2g$, where V = velocity in small pipe. Loss in gates and valves is uncertain, f full gate is about the same as in a length of straight pipe of 6 d.

draulic gradient. The conditions of flow in a pipe line may be clearly i by a graphical construction. Thus, Fig 14 shows a uniform diam pipe, urging freely in the air at With no flow the hydro- head at $A = h$. With k (from Bernoulli's the- $= h_p$, the press head, the velocity head, and, lering friction, $+ h_f$, or ad lost in pipe friction,

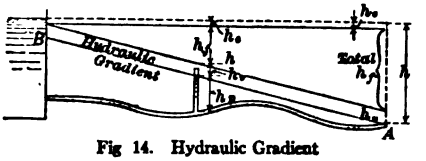

Fig 14. Hydraulic Gradient

Since there is no press head at A when there is flow, $h = h_v + h_f$, and for ondition this is true if h be taken as head causing flow. The lost head for ipe is made up of 2 parts: that lost in entrance h_e, and that lost in friction id, as friction loss varies directly with length and velocity head is constant the pipe diam is uniform, the different losses may be represented by the ical construction shown. Line AB is the hydraulic gradient, and repre- the height to which water would rise in a pressure tube inserted in the pipe y point. Fig 15 shows the hydraulic gradient for a compound pipe, neglect- ntrance loss and velocity head.

elocity of discharge may be obtained from the above formulas. In case of shown in Fig 14, with no bends, gates or valves, $h = h_v + h_f + h_e = \frac{v^2}{2g} + \frac{v^2}{2g} + 0.5\frac{v^2}{2g}$, or solving for $v = \sqrt{2gh \div \left(1.5 + f\frac{l}{d}\right)}$. Usually the velocity and entrance loss are so small compared to friction loss that the entire head y be assumed as consumed in friction, and $v = \sqrt{2gh \div f\frac{l}{d}}$. Discharge $= 6.30\sqrt{hd^5 \div fl}$. Diameter for a given discharge and head is $d = 0.4789 \div h)^{1/5}$. Though these formulas are fundamental they are seldom used in orm, as proper value of friction factor f is less well known than for other forms. ew smooth pipe $f = 0.02$, while for old pipe it may be 0.04 or even higher. sual formulas for flow are given below, following explanation of terms used.

ydraulic radius, or hydraulic mean depth $R = A \div p$, where A = area ss-section of flow and p = wetted perimeter, or length of boundary of cross- n in contact with water. For a circular pipe flowing full, $A = \pi d^2 \div 4$ and d, or $R = d \div 4$. For a rectangular flume 6 ft wide and 3 ft deep, $A = 18$, 2, and $R = 1.5$ ft. Hydraulic radius is a term that can be used with both and closed channels and hence is preferable to d.

pe of the hydraulic gradient S is expressed in various ways, usually as the sine of the of the hydraulic gradient and hence practically $= h \div l$, or the available head divided gth of pipe or channel. It is sometimes given in ft per mile, per cent, or ft per 1 000.

ezy formula (1775) is the most widely used formula in hydraulic work. probably the best available for designing canals, ditches, and large conduits pipes, while the Hazen-Williams formula (see below) is well suited to com- tions for smaller pipes. Chezy gives $v = C\sqrt{RS}$, where v = mean velocity, r sec, R = hydraulic radius, ft, S = sine of slope of hydraulic gradient $= h \div l$, C is a coeff depending on roughness of the pipe or channel, etc. By substi- g $d \div 4$ for R and $h \div l$ for S, this formula is evidently identical wi- above, except that f is substituted for the term $8g \div C^2$.

Kutter's formula. Value of C in the Chezy formula varies with smoothness of the channel and with R and S. Various attempts have been made to ... a formula for C, the best known being that of Ganguillet and Kutter (... ("Flow of Water in Rivers and other Channels." Transl by Hering and Trautwine, Wiley, N Y.)

$$C = \frac{\frac{1.811}{n} + 41.65 + \frac{0.00281}{S}}{1 + \frac{n}{\sqrt{R}}\left(41.65 + \frac{0.00281}{S}\right)}$$

where R and S are as above and n is a factor depending only on the roughness of pipe or channel. Kutter gave the following values for n: 0.009 for well-planed timber; 0.010 for neat cement; 0.011 for cement with ¼ sand; 0.012 for unplaned timber; 0.013 for ashlar and brickwork; 0.015 for unclean surfaced sewers and conduits; 0.017 for rubble masonry; 0.020 for canals in very firm gravel; ... for canals free from stones and weeds; 0.030 for canals with some stones and weeds; ... for canals in bad order.

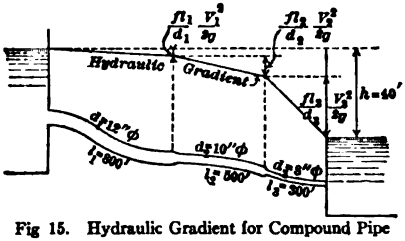

Fig 15. Hydraulic Gradient for Compound Pipe

Kutter's formula is purely empirical, but has been so widely accepted that several ... have been devised to facilitate its application. The most satisfactory is a diagram such as the accompanying, which solves the Chezy formula using the Kutter formula for C.

The diagram, Fig 16, by K. R. Kennison, (*Eng News*, June 20, 1912), was published with explanation in extended form, 1913. Example 1. A wood-stave pipe is 6 ft diam and 2 miles long. Available head, 10 ft. If n is 0.011, what are Q and v? $R = \frac{6}{4} = 1.5$. $S = 0.95$ ft per 1 000. Enter lower part of diagram at A, with $R = 1.5$, and ... (as shown by arrows in Fig 16a) to intersection with "n" line for $n = 0.011$ (interpolated) and run vertically upward to intersection with "S" line in upper part, where the velocity (=5.7 ft per sec) is read on the vertical scale. $Q = 0.785 \times 6^2 \times 5.7 = 161$ cu ft per sec. Example 2. An ordinary riveted steel pipe, 4 ft diam and 5 000 ft long, is to carry 60 cu ft per sec. $n = 0.016$. What head is required? $R = 1.0$ ft, $A = 0.785 \times 4^2 = 12.55$ sq ft, hence $v = 60 \div 12.55$ or 4.8 ft per sec. Start at A as before, running upward from the intersection with the "n" line and locating a point corresponding to B in Fig 16a on this vertical line and on a horiz line representing $v = 4.8$. The position of B with respect to the slope or "S" lines gives the required slope = 2.5 ft per 1 000, or a total head of 12.5 ft. For other problems see Art 15. (Note that when s is small several lines are given for each slope, to be used for different values of n.)

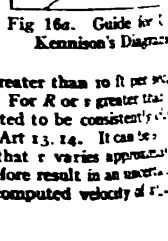

Fig 16a. Guide for ... Kennison's Diagram

Limits of application. Kutter's formula is best used for velocities between 1 and 6 ft per sec, but is fairly reliable up to 10 ft. For hydraulic radii greater than 10 ft, velocities greater than 10 ft per sec, slopes flatter than 1 in 10 000, it should be used with caution. For R or v greater than ... it is unreliable. Results from the formula must not be expected to be consistently ... than 5%. For values of n recommended for use in design see Art 13. 14. It can be ... that S varies as n^2 for values of R greater than 1 ft, and that v varies approximately inversely as n. An uncertainty of x% in selecting n will therefore result in an uncertainty in a computed slope of twice this amount, or $2x$%, and in a computed velocity of ...

Hazen-Williams formula (Hydraulic Tables. Wiley, N Y, 1905) is an ponential formula, $v = 1.318\,cR^{0.63}S^{0.54}$, based on following reasoning Ch formula may be written $v = CR^{0.5}S^{0.5}$, and if its exponents agree perfectly w the facts the value of C would depend on roughness only. But, the values the exponents must vary with different surfaces, diameters, slopes, etc. Has Williams formula uses exponents representing aver conditions; the value of which varies with different surfaces and sections, but has a smaller range than is selected from experience, not computed by a formula. The quantity c is introduced simply to make the value of c about the same as that of the Kut or Chezy constant C. Hence, Hazen-Williams formula is probably less accur than the Chezy; but, since in most computations it is simply a question of sele ing a pipe of some standard size, great accuracy is not necessary.

Hazen-Williams advise following values of c: for very best C-I pipe, 140; good new pipe, 130; tuberculated C-I pipe, 80 to 110; designing C-I pipe, 100; new riveted s pipe, 110; ordinary W-I pipe, 100; lead, brass, tin pipe, 140; smooth wood pipe, 1

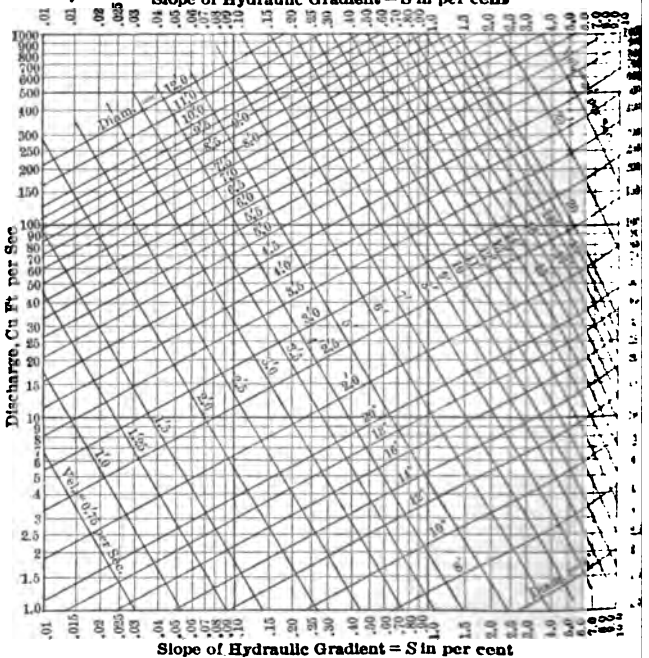

Fig 16b. Diagram for Solving Hazen-Williams Formula

brick sewers, 100; vitrified pipe, 110; smooth clean masonry, 140; slime-coated masor 130; ordinary good masonry, 120.

The diagram, Fig 16b (S. D. Bleich, *Eng Rec*, Nov 30, 1907), is convenient for s Hazen-Williams formula. It is constructed for $c = 100$; for other values of c m the required discharge by $100 + c$, and the resulting value of q must be used to get size of pipe and velocity. Then multiply this velocity by the ratio $c \div 100$ to get

alue. **Example 1.** A C-I pipe is to carry 10 cu ft per sec, length 1 000 ft, available head Using $c = 100$, find required size? $S = 1$ ft per 100, and running vertically from this in the diagram to the intersection with the horiz line representing a discharge of 10 cu ft c, the intersection is found to be slightly below the 18-in diam line, indicating that an pipe is needed, and the mean velocity is found to be slightly less than 6 ft per sec. ple 2. A wood pipe is 4 000 ft long, and is to discharge 60 cu ft per sec with 20-ft ble head. Find d and v. In this case $c = 120$. Multiply Q by 100 ÷ 120, giving $Q =$ d enter the diagram with this value and a slope $S = 0.5$ ft per 100, as before. Hence, 8 in and $v = 6.5$ ft per sec. Actual v will be $6.5 \times 1.20 = 7.8$ ft per sec.

mpound pipes. Algebraic expressions can be derived giving exact relations een discharge and head for compound pipes, but it is simpler to solve these ems by determining size of a single pipe that will be equivalent to the given ination; that is, such a size as will give same loss of head for a given discharge.

example, find the discharge from the compound pipe in Fig 15. Take $c = 100$ in -Williams formula. Assume any convenient and reasonable Q, say 3 cu ft per sec. Hazen-Williams diagram find for the 8, 10, and 12-in pipes the required grades or head in per cent, viz, 5, 1.8, and 0.7 for this Q, which, multiplied by the respective s, give 15, 9, and 5.6 ft, or a total of 29.6 ft necessary head. As the total length is ft, this represents an aver loss of 1.85 ft per 100, and the uniform pipe which would discharge of 3 cu ft per sec with this hydraulic gradient would be (from diagram) 9.8 in diam. Actual available head is 40 ft ($S = 2.5\%$), and Q for a 9.8-in pipe his head is 3.5 cu ft per sec, the required value.

nch pipes, as shown in Fig 17*a*, may be solved similarly. First find size of uniform o replace *BCDE*, as above. This is found to be 8.8 in. Now the loss of head be- *B* and *E* must be the same by outes, *BE* and *BCDE*. Assume asonable loss of head, say 15 ft, ind discharge by each route. e *BE* pipe (10 in, 600 ft long), .5 ft per 100, and from diagram .7 cu ft per sec. For the 8.8-in 200 ft long, $S = 1.25$ and $Q =$ The total discharge = 5.5 cu ft c, and the diam of pipe 600 ft hich will deliver 5.5 cu ft per der a head of 15 ft is found he diagram to be 11.5 in. The m is thus reduced to that in 5, which when computed as for compound pipes, assuming f 6 cu ft per sec, gives uniform f 11.9 in, the discharge for 2 400 hich under a 50-ft head is 5.2 per sec.

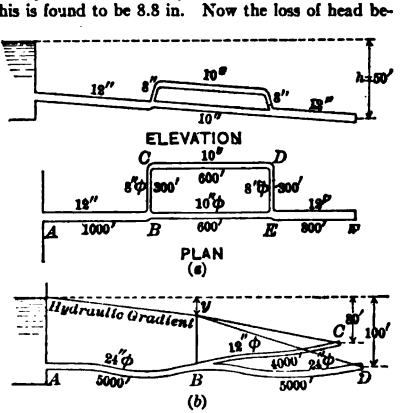

Fig 17. Branch Pipes

17*b* shows another problem in pipes. It may be solved alge- lly, but more easily by trial. A portion y of the head up to the fork must be used up in causing a discharge through at will just equal the sum of the discharges through *BC* and *BD* under the remaining $80 - y$ and $100 - y$. Value of y is best found by trial. From Fig 17*b*, since lengths id *BD* are same, it is evident that y must be more than 50, and by a few trials it is that $y = 58$ will give satisfactory results, the total discharge being 23 cu ft per sec = 2.6 and *BD* = 20.5).

pen channels. The usual formula for flow is the Chezy, with the Kutter given above. In open channels or conduits, not flowing under pressure, the ulic gradient coincides with water surface. R may be obtained from cross- ns, and is generally about equal to mean depth of channel. Right-angle bends sually considered as causing a loss equal to $v^2 \div 2g$, the velocity head, which e small, since velocities are very low. For design of canals, see Art

DESIGN

12. Kinds of Pipe

Standard sizes. In computing the necessary diam for a pipe no great de of refinement is ordinarily necessary, as it reduces to a question of selecti standard size. The relative discharge capacity of pipes vary as the five ha power of the diam (about) and is shown below, using a 4-in pipe as 1. An pipe will carry 6.5 ÷ 3, or over twice as much as a 6-in pipe, hence no very a rate computations are necessary to determine which is required.

Diam.....	4	6	8	10	11	14	16	20	24	30	
Relative capacity...	1	3	6.5	12	20	30	43	80	130	235	3

Cast-iron pipe. Standard sizes are 4, 6, 8, 10, 12, 14, 16, 18, 20, 24, 30, 3 48, 54, and 60 in, usually made in 12-ft lengths, with bell and spigot (Fig 1 flanged joints (Sec 41, Art 7). The latter is use pump connections, etc, or wherever it may be occas ally necessary to remove sections of pipe. Bell and s is common for water and gas mains. The joint is m by first packing with oakum, then pouring a collar of around the bell, which is afterwards calked tight (T.

Fig 18. Standard C-I Pipe, Bell and Spigot Joint

Cement joints are commonly used for gas mains. Pipe is made in standard and thicknesses (Table 3). For large orders any desired thickness is obtain

C-I pipe is cast in 12-ft lengths, bell down, and cleaned and dipped in hot tar and ba oil for a protective coating. C-I pipe is subject to formation of tubercles of rust or inside (particularly when used for impure water or water containing free CO_2), seriously affects its carrying capacity, but usually without greatly imparing its str Probably Hazen-Williams formula (Art 11) is the best to use in design, and while the of c may be as high as 140 for new clean pipe, about 100 must be used if the carr capacity is to be maintained over a period of years. Care should be taken in layin pipe that "bell holes" are dug for the joints, so that the pipe will have a firm suppor its entire length and not rest on the ends; for large sizes the back fill should be well ta under and around the pipe and for a depth of 2 or 3 ft over it, to relieve the pipe excessive external loading. Ashes in refill should be avoided.

C-I pipe has an aver life of 40 to 80 years or more. Cost varies considerably, avera between $26 to $30 a ton. Special shapes, as Ys, Ts, curves, blow-off branches average $60 a ton.

Wrought-iron pipe was formerly made in considerable quantities, but has been pr cally replaced by mild steel (frequently sold as wrt iron). The relative durabi of two materials has long been a matter of dispute, but since in 1916 only 1 or 2 U S make a real W-I pipe, there is seldom opportunity to choose between them.

Steel pipe is of several forms: welded, ordinary riveted, spiral rivete lock bar. BUTT OR LAP-WELDED PIPE is made of mild steel, from ¼ to 15 in. inal diam (actual internal diam varies. Sec 41, Art 7).

It is used for steam and water connections in mechanical work, for interior p water supply, gas, heating, etc, and for supply pipe lines and pumping. It is the st pipe for most service, when the required size is 10 or 12 in or less, except street supply mains. Quite recently the manufacture of lap-welded pipe of larger sizes ha developed; it is now made up to 72 in diam, and is used in water-power work heads, where the saving in metal due to its greater joint strength and perfectly s interior make it more economical than riveted steel pipe.

Riveted steel pipe is used chiefly in large sizes and for high heads. made of curved sheets, the longitudinal edges of which are joined usually double-riveted lap joint, although in larger sizes butt joints double or t riveted with single or double cover plates are used.

s up to 30 in diam are sometimes made of single sheets in 12 or 15-ft lengths. Larger re made with single-riveted lap joints. Field joints between the lengths are made eral ways. For low pressure and pipes up to 40 in diam, a slip joint may be used. ve is placed inside and attached to one end of the pipe, which is covered with burlap vas coated with red lead or asphaltum and then driven into the end of the next length eld by wire ties. For higher pressures, the pipe ends are riveted to forged steel s, connected by bolts and gaskets. Fig 19 shows several kinds of joints. Bolted are also used, which not only act as expansion joints but also allow a slight deflection ermit straight pipe to be laid on easy curves. Lengths of large pipe are usually d together in the field. For design of riveted joints see Sec 43, Art 29.

iral-riveted pipe is frequently used for smaller heads and in sizes up to 42 ec 43, Art 29).

s made in 15-ft lengths galvanized, and 30 or 40 ft, asphalt coated. Each length is ingle sheet, rolled with overlapping edges forming a single-riveted spiral seam. This an efficient joint against bursting, and the seam is said to be the strongest part

pipe. In large sizes it is not made thicker than 0.25 in, and though used for orda water or low-head pipe lines, finds its best application in construction work where its s strength as a b saves necessity of quent support, for its strength, the lightest steel made.

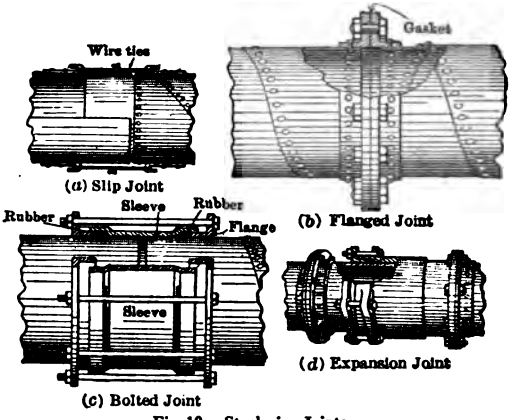

Fig 19. Steel-pipe Joints

Lock-bar pi a form of steel in which a 100 ficient joint is tained by bendi plate of steel t proper form. edges, first u are inserted in open grooves "lock bar" or H-section, whi closed over the set edges by a draulic press.

Life of steel pipe depends on so many factors that it can be given only general terms. Unlike cast iron, which rusts more or less uniformly, steel o pits through in places. Thin steel pipes, ⅛ in or even less in thickness, lasted 15 or 20 years. A thickness not less than 0.25 in should give a use of 25 years or more.

Carrying capacity of small sizes of steel pipe may be found by the Hazen-Wi formula (Art 11). For large, riveted pipe, with rivet heads and seams projecting o side, the Chezy formula is often used with $n = 0.016$. Formula $V = 1.34 D^{0.7} H^{0.555}$ is also used, where V = veloc, ft per sec, D = diam, ft, and H = loss of head, ft per 1 000.

Wood pipe has 2 forms: continuous-stave pipe, built in place, and machine-banded pipe made in lengths in factories.

Continuous-stave pipe has been built up to 14 ft diam; it is rarely made less than 2 ft diam. It is best adapted to moderate pressures, from a minimum of 20 ft head (considered necessary to keep the wood saturated and prevent decay) to a max of 200 to 250 ft. Advantage for large diam pipe: low cost, great carrying capacity ($n = 0.009$ to 0.011 in Kutter's formula) easy transport of material, curves of moderate radius readily made, less liable to freeze than greater strength against deformation than thin steel. Staves are milled with radia to form true circular inside and outside surfaces. They have a length of 10 ft and averaging 16 ft, and are placed so as to break joint by 2 ft. Joints between ends are made by metal tongues inserted in saw kerfs (Fig 20). Hoops are usually of mild steel, in one piece for pipes up to 54 in diam. They have button head on one end cold-rolled threads for 5 in or more on other end, which is often upset to make thread

Fig 20. Continuous Wood-stave Pipe

as body of bar. Ends of hoop rest in a malleable iron shoe, and the band is cinched a hexagonal nut. All metal work is heated and dipped in a mixture of asphalt and oil, and is touched up after placing. Pipe is built by using an outside form for lower building up both sides at same time, and an inside form for upper half resting on half. Sharp curves are to be avoided. A radius of 60 times the diam is the usual m, but this has been exceeded. MATERIAL FOR STAVES is usually Redwood, Douglas Oregon yellow pine. Redwood is considered by many to be too soft. Staves are from standard thickness of lumber for each diam.

Diameter of pipe	Nominal thickness of staves
10 to 14 in	1.5 in thick, 4 in wide
16 to 48 in	2 in thick, 6 in wide
54 in	2.5 in thick, 8 in wide
60 to 72 in	3 in thick, 8 in wide

ual dimensions of staves vary with each diam. The only computation made is for ed spacing of bands. BANDS. If safe strength of band (lb) = S, then $S = fvt^2$, f = safe tensile strength, usually 15 000 lb per sq in, and r = radius of band, in. may cause failure by breaking in tension, or by crushing the wood fibers. The safe ing load on wood can in this case be taken as 650 lb per sq in. Width of bearing of on wood is taken = t, and some specifications require that band be hammered into od until this bearing is secured. Hence, safe load on band would be $S = (R + t)$ where R = radius and t = thickness of pipe, in. For economical design, diam of should be such that values of S figured from either formula are equal, or $r = 0.0138$ t). Diams of ⅜, 7/16, ½, ⅝, ¾, and ⅞ in are used. SPACING OF BANDS is determined e hoop tension due to water press, and by the tension produced by swelling of the

Using the minimum S (see above) the spacing of bands, in = $S + (pR \times et)$, p = water press, lb per sq in, and e = swelling force of the bands, which cannot l the compressive strength of wet wood and may be taken as 100 to 125 lb per sq in. OF WOOD PIPE is very variable, depending on conditions under which it is used. A pipe line, with a cover of 2 ft or more of clean soil free from alkali or vegetable r and maintained under a head of 20 ft or more, will have a longer life (25 to 50 than a line above ground. Under less favorable conditions, life is 6 to 15 years, he pipe is best supported on cradles or sills. Connections are made by inserting Ts or branches in the line, to which the wood pipe is firmly secured. Approx cost in dollars, of fir continuous-stave pipe, erected exclusive of earthwork or cradles, is:

m, in.	24	30	36	42	48	54	60	66	84
ft head	1.40	1.50	1.60	1.75	2.25	2.75	3.30	4.00	5.25
" "	1.75	1.90	2.00	2.25	2.80	3.25	4.00	5.00	6.50

achine-banded pipe is built in the factory in s of 8 to 20 ft and diam ranging from 6 to 48 in, y not over 24 in. Pipe is of staves with edges d to form tongue and groove joints, banded with galvanized steel wire, wound spirally by machine high tension. Wire is from No 8 to No 0, size pacing being regulated according to the press. teel bands are also used. The outside of the pipe vily coated with hot asphalt and tar, and rolled dust to make it better to handle and ship. The ed joint (Fig 21*a*) is for pipes up to 14 in diam. oden collar (Fig 21*b*) or wood-sleeve coupling is on larger sizes. This form has been used for supply pipes, instead of cast iron, also in hy- ic mining, and is useful for same service as con- us pipe, but where smaller sizes are required.

STANFORD LIBRARIES

mula $t = \frac{1}{2} d\sqrt{h \div f}$ may be used in design as a rough check, t, d, and f, in, being as for hoop tension, and h = depth of fill, ft. Wt of fill is say 100 lb per cu ft, and h ally taken at 0.5 to $\frac{2}{3}$ the total depth, to allow for arch action. The amount and ution of load is uncertain. Formula assumes the load to be uniformly distributed he upper half of the pipe, and that it is resisted by uniform press over the lower half. roduces a moment in the shell M, in-lb per in of length = $\frac{1}{16} Wd$; where W = total er linear in of pipe and d = diam, in. A concentrated load produces a positive nt $M = 0.159\ Wd$ at top and a negative moment = $0.091\ Wd$ at sides. Careless ll may cause some other mode of loading (*Bull* No 22, Univ of Ill Expt Sta, 1908).

ernal pressure, due to the pipe being placed above the hydraulic nt, or to lack of or inadequate air valves, has often caused collapse of thin pipes. It is important only in lines of this kind.

n the internal press becomes less than atmospheric, the shell is subjected to a uni- xternal press = p = difference between atmospheric (14.7 lb per sq in) and the te internal press; this causes circumferential compression in the pipe shell. The ing pressure for steel pipe, lb per sq in = p = about $50\,200\,000\,(t \div d)^2$. Air of too small a size may require a greater suction head than this amount in order to air fast enough to fill the pipe when it is emptied quickly, intentionally, or due to . It is generally more economical to provide one or several air valves of ample area summits, than to increase the pipe thickness or to provide flanges to increase its ing strength (*Eng Rec*, May 23, 1915, p 594).

ading stresses due to wt of pipe and water are important in large steel nder low heads. They are usually provided for, not by increasing the ess of shell, which is uneconomical, but by placing a concrete saddle under pe, or by riveting to the pipe at short intervals curved hoops made of with an outstanding edge.

mum moment occurs at bottom of the pipe, and is due to the water load. M, r lin ft of pipe = CwR^3, where C depends on angular length of the saddle (the angle er of pipe subtended by the saddle) and has the following approx values: for $C = 0.75$; $\alpha = 15°$, $C = 0.56$; $\alpha = 30°$, $C = 0.42$; $\alpha = 45°$, $C = 0.32$. W = ater, lb per cu ft (= 62.5) and R = radius of pipe, ft (*Eng Rec*, Jan 31, 1914, p 133). g R and α, it is possible to test a pipe for bending due to this cause, the fiber stress hell being found by the usual formula (Sec 43, Art 4), and if necessary the size and required for angle stiffeners are computed.

perature range of a pipe depends on whether it is covered and on its size. A short e of large diam full of water has a temp range nearly equal to that of the water 32° to about 80° F); a long covered pipe line of small diam has a temp range nat of the soil, which depends on depth of cover and seldom exceeds 40° F for a r. If uncovered and with low flow, a small pipe may have a range almost equal f an empty pipe. Variations in temp produce longitudinal stresses in a pipe that so as neither to contract nor expand, the direction (tension or compression) and of which depend on the temp at which the pipe was laid. These stresses may ckling, and in many exposed pipes EXPANSION JOINTS are provided at intervals top of saddles are made smooth to allow expansion and contraction without exces- ion. Fig 19*d* shows a common expansion joint. These joints are usually placed w the anchorages on exposed pipe lines, and as anchorages occur at all bends at expansion joint is required on each straight portion of the pipe, and intermediate n joints are desirable on very long stretches of straight pipe.

14. Design of Pipe Lines. Valves and Anchorages

eral pipe lines should be kept below the hydraulic gradient (Art 11). If above it siphon action is created, which is undesirable because: (*a*) it s with the action of the pipe line and usually causes decreased or uncer- harge; (*b*) the pipe at high points is under external pressure and liable se. A profile of the proposed line should therefore be carefully studied ng the hydraulic gradient.

Fig 23 shows profile of a pipe line. If a uniform diam is used from *E* to *B*, laid on face of the ground (*ECB*), and the pipe discharges freely at *B*, the hydraulic gradient run from *A* to *B*, provided the pipe is first fi and then a valve at *B* opened. Part of the near *C* will be above the hydraulic gradient, therefore subject to what is termed nega press, but which is really negative only in sense of its being less than atmospheric, 5 ft than zero. As long as *CF* is not over 34 ft, the pipe will act as a siphon, discha under the head *h*. But it is almost impo to make the pipe tight, and air will collect and finally break the suction action. The

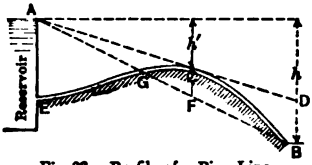

Fig 23. Profile of a Pipe Line

will then discharge at *C*, under the head *h'*, the hydraulic gradient running from *A* to *C*, a certain quantity of water *Q*, less than the remaining portion *CB*, could discharge under head $h - h'$. The portion *CB* will therefore carry off this *Q*, flowing only partly full.

This action may be avoided in several ways: (*a*) Valve at *B* may be partly closed causing the gradient to rise to *D* and acting as an orifice, the discharge of which under head *DB* just equals the discharge of pipe under head $h - DB$. This does away with negative press at *C*, but the discharge of the line is less than with siphon action. Such throttling of the valve at *B*, even if it is not opened more than the necessary amount stated, may cause the "accelerating gradient" to fall below *C* until the water gets in motion, normal conditions are reached, so that air valves should be placed at *C* if there is danger of collapse; (*b*) if constant operation is unnecessary and negative press not liable to cause collapse, the valve at *B* may be closed at intervals which puts the pipe at *C* under a press equal to head *h'*. A valve at *C* may then be opened and air allowed to escape. It would be advisable in this case to place a large air receiver at *C*, to collect the air, a tank above the pipe and not decrease the pipe section at this point; (*c*) a trench may be dug from *G* to *B*, to keep the pipe below the gradient, but this may be costly; (*d*) a compound pipe may be used, and this is often the most satisfactory method. A large pipe used from *E* to *C*, to deliver say 10% more water under the head *h'* than a smaller size, running from *C* to *B*, will deliver under the head $h - h'$.

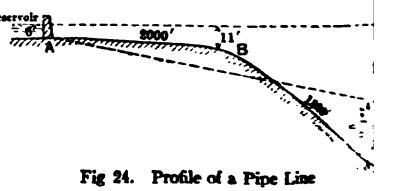

Fig 24. Profile of a Pipe Line

Example (Fig 24). Pipe line from *A* to *C* is to deliver 2 cu ft per sec at *C*, with a terminal press of 25 lb per sq in (= 25 × 2.30 = 57.5 ft head). If the pipe delivers this quantity when reservoir is empty, available head causing flow = 130 − 6 − 57.5 = 66.5 ft. For a 12-in pipe, with slope 1.75 per 100, and *C* = 100, *d* = 8.6 in (Fig 16*b*); hence, use a 12-in pipe. Using this, the gradient will be *AC'*, with siphon action present. Also a 14-in pipe is required to keep gradient above *B*, and flow at *C* must be throttled. a compound pipe for *BC*, the available head = 130 − 11 − 57.5 = 61.5 ft (slope per 100) and nearest standard size (Fig 16*b*) is 8 in. With this head an 8-in pipe will discharge 2.4 cu ft per sec. For the *AB* section the available slope (reservoir empty) is 0.25 ft per 100, and a 14-in pipe gives 2.5 cu ft per sec.

Fig 25 shows hydraulic gradient for conditions arising in pumping through pipes. (*a*) shows conditions in pumping from *A* to *B* against static head *AC*, and that the pump under total head *AD*. In a pipe line for pumping it is usually economical to keep velocity (and hence friction head) low; say between 1.5 and 3 ft per sec, depending on cost of power of pumping. In designing line *AB*, an economical velocity is computed or assumed, and diam of pipe found for required discharge. Friction head is then found from diagram.

In case *b*, if pipe *AFB* is once filled it would discharge under head *AC*, as in Fig *a*, hydraulic gradient running from *A* to *B*, provided distance *EF* does not exceed about 34 ft. If water is pumped through pipe *AFB*, the friction head is *DC* and the pump acts against head $DC - AC$, provided *FE* is as stated above. If *FE* be greater, the hydraulic gradient changes to that shown in case *c*, the pump then acting under head *AE*, and the part between *F* and *B* carrying off the discharge at *F* and flowing only partly full.

gative press is not permissible at *F*, the hydraulic gradient must be kept above *F*. in be done: I, by increasing the head against which the pump is working to head *AG*), which involves a smaller ith increase of velocity and head for the same dis- ; II, by designing a pipe n *A* and *F* that will give an nical velocity and using a om *F* to *B* that will just off this discharge, under *H*; III, by placing a valve nd throttling the flow as in . Here the gradient may sed to line *EG* and kept *F*. In this case air valves be placed at *F*. If it is to take advantage of gra- *DB* (case *b*), steel pipe is ary for the part above the nt, made thick enough to and the difference in press 3), or C-I pipe might be There must be a valve at prime the siphon.

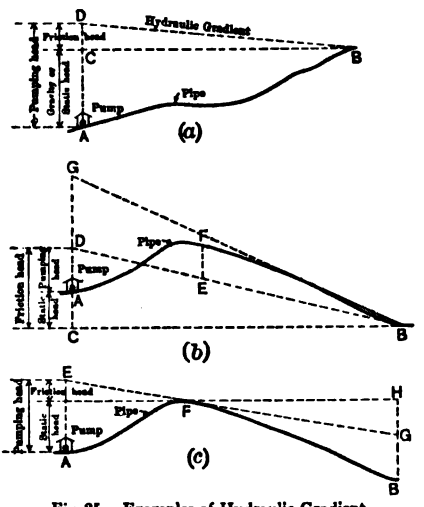

Fig 25. Examples of Hydraulic Gradient

ves. Fig 26 shows the of a pipe line, with loca- f valves. AIR VALVES, to t escape of air on filling, ntrance of air on emptying, aced at every summit and it-off valves. For a shallow reservoir best type of air inlet is a simple standpipe, above water level in reservoir. Air valves are often automatic; float valves have sed, automatically permitting escape of air collecting at summits. Air collects at mmits, and must be removed, as by ordinary gate-valves operated by hand. The ity of ample air valves to prevent formation of vacuum in steel pipe lines has been sed. BLOW-OFF VALVES are placed at low points in pipe lines for emptying the when necessary and for removal of sediment. These are gate-valves, placed on a pipe (about ⅓ the diam of main pipe) leading to discharge in a stream or waste el. SHUT-OFF OR STOP VALVES (ordinary gate-valves) are placed at end of pipe, and, g pipes, at intervals of 1 to 2 miles along the line. This permits inspection and repair section, without emptying the entire line, and in case of breakage water may be shut nearest valve, thus preventing wastage and serious damage. These valves are usually l at summits, with air valves on each side. A lock and chain are put on all valves to at tampering; on large lines the valves are in covered manholes with locks. For large diam lines, a small by-pass pipe with separate valve is added; it is left open to relieve the press while the large valve is being closed. Cost of gate-valves increases rapidly with the sizes; a saving in cost at a slight loss in head may tained by decreasing the diam of pipe at points where valves are placed by using le reducers and tapering increases. CHECK-VALVES are used mainly on pump lines, at where breakage would permit large backward flow of water, as at foot of inclines (at *A*, 5a, *b* and *c*), and on inlet pipe just outside tanks or standpipes. For small sizes a alve is used. For pipes larger than 24 in, a diaphragm or valve plate is cast in an ted section of the pipe, and a number of small valves attached to holes in the plate. all by-pass is sometimes used to avoid heavy water-hammer, caused by sudden g of valve with pulsations of pump. RELIEF (SAFETY) VALVES are occasionally used ls of long pipe lines, or wherever water-hammer is especially to be feared The g disk valves, opening outwards and held in place by springs adjusted to the

alined ditches in earth. The CROSS-SECTIONAL PROPORTIONS in Fig 29 not used, because they give sections that are too narrow and deep. Such ons are unstable; they will widen out on the sides and silt up in the center, are seldom economical to dig, as scrapers are generally used and a shallow s necessary. Deep narrow ditches require shoveling.

per proportions are largely a matter of judgment, depending on character of soil and of excavation. Average U S practice is to make $D = 0.5\sqrt{A}$, where D = depth, d A = area, sq ft. This rule gives following depths:

Area, sq ft.....	5	10	25	50	75	100	200	400
Depth, ft.....	1.1	1.5	2.5	3.4	4.3	5.0	7.1	10

e values are exceeded for special conditions, as on steep hill sides where a narrow, section (with lining for stability if necessary) is often economical in excavation. e water carries much silt the section may be shallower. Usual SIDE SLOPES are 1 : 1, 1, and 2 : 1. On steep hillsides in firm soil a 1 : 1 slope both for ditch section and side slope of bank is used. Any section gradually becomes rounded, the lower parts e slopes becoming flatter, the upper parts steeper. For aver loam or gravelly loam,

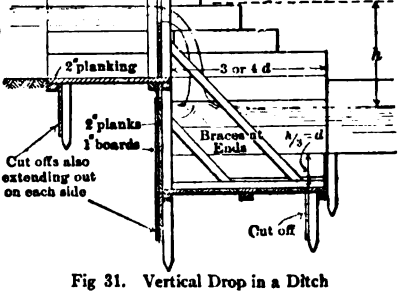

Fig 31. Vertical Drop in a Ditch

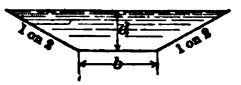
e above figures show that for es in earth the usual velocity o 3 ft per sec, which generally requires a slope of 4 to 7 ft per mile. A section ned as in the example following, and located to have the required slope; or, if

is fixed and small, it may be necessary to line the ditch to obtain the required discharge. the other hand, if a large slope is available, the ditch may be excavated at the max desi slope, and the extra head used up by constructing CHUTES or DROPS, commonly designe water-cushion or baffle spillways (Fig 31). In some cases where no supporting groun available, the ditch must be constructed on the given slope and lined to prevent erosi

Chezy formula, with C determined from Kutter's formula, is generally for ditches and flumes. Most engineers take $n = 0.025$ for aver earth actually ranges from 0.02 for firm soil, trimmed smooth with a shovel, to for rough gravelly surfaces, the aver for most irrigating ditches in Western being 0.0225.

Example. Design a ditch in earth to carry 2 500 miner's inches of water, and comp the required slope. Assume $n = 0.025$ and safe velocity = 2.5 ft per sec. Discharg



$A = bd + 2d^2$ $R = A \div (b + 4.48d)$

Fig 32. Cross-section of Ditch

2 500 ÷ 40 = 62.5 cu ft per sec, and required area = + 2.5 = 25 sq ft. Desirable depth = $0.5\sqrt{A} = 2$ With 1 : 2 side slopes, area will be $bd + 2d^2$ (Fig 32). $b = (25 - 12.5) \div 2.5 = 5$ ft. Hydraulic radius $R = A$ $(b + 4.48d) = 25 \div 16.2 = 1.54$ ft. Using the diagr (Art 11, Fig 16), the required slope is found to be 1. per 1 000 ft.

The center line of the ditch should be so located t the cut will make the required fill plus the shrinkage, except where it is advisable to b the water section entirely in cut because of danger from breaks. Breaks are especia be feared on steep hillsides, even when the sod under the fill is furrowed with a plow to g a good bond between the fill and original ground surface.

For level cuttings with 2 banks the economic cut x is computed to balance the sect (Fig 33a). For side-hill work, 1 bank only is generally required, and the "pivot-point method of locating the center line is used (Fig 33b). The section *ABC-DEF* being designed, a horiz line *LP* is drawn through the section, so that cut *LBCN* makes the fill *NDEP* plus shrinkage (usually 10%). Line *LP* is then divided into 2 parts by point *M*, equal if no allowance is made for shrinkage, or for 10% shrinkage such that $LM : MP :: \sqrt{100} : \sqrt{90}$. *M* is the pivot point, and for any slope as *AF* drawn through *N* the cut will balance the fill. *M* must thus be located on the ground as a p on a grade contour x ft above the bottom of the ditch, and the center line will be a di tance y up hill from *M*. x and y are independent of the slope of the side hill, and rem the same for any given cross-section.

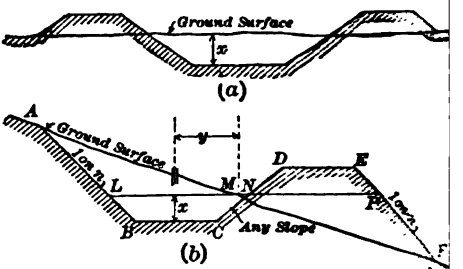


Fig 33. Balancing Cut and Fill

16. Losses in Ditches and Canals, Ditch Structures, Flumes

Seepage losses often amount to 25% or more of the water delivered at upper end of the ditch, and must be allowed for in computing the carry capacity. The loss depends on the character of the material in which the d is excavated, whether it is or is not lined, on the relation of the water level ditch to the water level of the adjacent ground, and on the age of the ditch the ditch is below groundwater level, there will be inflow from the adjoining la and vice versa. In many cases the ditch is above groundwater influence. and the seepage loss may be computed from the following table (Etcheverry):

Material	Loss, per 24 hr, per sq ft wetted perimeter	Material	Loss, per 24 hr, per sq ft wetted perimeter
pervious clay loam	0.25–0.35	Sandy loam	1.00–1.50
dinary clay loam, silt, or lava ash loam	0.50–0.75	Loose sandy soils	1.50–1.75
avelly clay loam, sandy clay oam or cemented gravel	0.75–1.00	Gravelly sandy soils	2.00–2.50
		Porous gravelly soils	2.50–3.00
		Very gravelly soils	3.00–6.00

itch linings are to prevent excessive seepage losses, or to permit higher rities than are permissible in earthy soils. Higher velocity is advisable in cases for economy, the cross-sec and seepage loss being smaller; and in cases where topography is such that supporting ground is not available combination of earth ditch and vertical drops or chutes to use up excessive

tails. About 3 gal heated heavy asphalt road oil per sq yd, applied in 2 or 3 doses and raked into the upper 2 or 3 in of the soil, will reduce seepage loss to about of value for untreated. It also prevents growth of vegetation and allows increase in ity to about 5 ft per sec, but is not permanent, requiring renewal every 2 to 4 years. PUDDLE, consisting of a 3 to 4-in layer of well-tamped clay, is as effective in stopping ge as oiling, but does not allow any higher velocity or prevent growth of vegetation. planking, nailed to sills set in sides and bottom of ditch is effective, but due to high and short life is seldom as economical as cement or concrete. CEMENT MORTAR 1 cement to 4 sand, 1 in thick, will prevent 75% of the seepage. CONCRETE lining, 4, 2 to 4 in thick, will stop 95% of the loss. The concrete is placed with or without On slopes of 1 to 1 or less, no forms are used, the lining being placed like cement alks, grooved every 8 or 12 ft to reduce width of contraction joints by making them at frequent intervals. For steeper side slopes heavier side linings are required and are used. Instead of trimming the bank to correct slope, it is best to use an out- form, filling in with wetted earth up to this form, and using an inner form for the ete. A solid foundation is important, as the concrete has little strength and will if foundation settles or pockets are washed out under it. Also, proper drainage is tial to keep material compact and dry, and to prevent heaving due to frost. Cost s from 3 or 4¢ per sq ft for cement linings 1 or 1.5 in thick, to 18 to 25¢ for 3 or 4-in ete linings.

tch structures. TURNOUTS are to distribute water from main ditch to laterals. For ditches, a wooden box will answer; for larger, where repairs would be costly, a anent vitrified or cement culvert is desirable (Fig Connections of siphons, rts, flumes and turnouts, n earth ditch must be ully made, to prevent ge at these points, with er of a washout. CHECKS hold flow-back, so as to ly a turnout with proper nt of water. They are times also used as small s (Fig 31) to decrease rade. CHUTES are long, sections on a steep grade, a water cushion at the bottom to kill high velocity. WASTEWAYS are overflow to carry off flood flows, or turnouts to a stream channel which act as blow-offs to y the ditch. They are installed on many long lines.

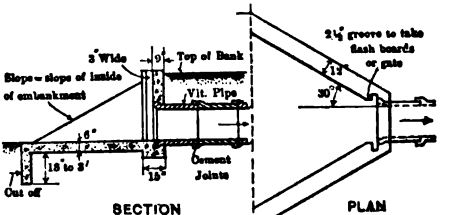

Fig 34. Turnout from Ditch

umes (Fig 35) are used to cross valleys, and on hillsides where the slopes oo steep or the soil is unsuited to an open ditch. The latter are called bench es. **Breadth** of flume box is generally twice the water depth (Art 15).

Bench flumes are often narrower, and trestle flumes wider. Freeboard (in) m be made equal to (depth of water in ft + 12) + 2. Flume lining should be o in, or better 2-in plank.

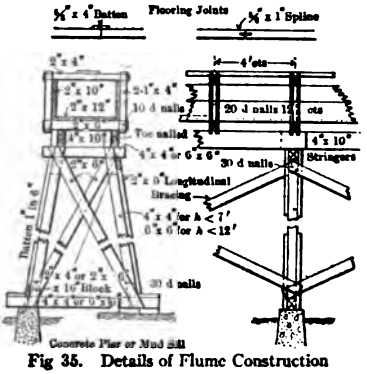

Fig 35. Details of Flume Construction

There are 2 forms of flume bot sills are placed across the stringers, flooring is laid parallel to direct flow like the sides; (*b*) flooring is tr verse and nailed to stringers. The is best and easiest to keep tight repair. Foundations and sills ar 2 × 12 or 3 × 12-in plank or con posts. Bents are spaced 12 to 15 ft ters, and stringers are designed to the load at a low unit stress. Sem cular continuous wood-stave pipe also been used for flumes; now replaced by semi-circular steel flu Several patented forms, made in R ver and San Francisco, are moderat cost, easily and quickly constructed watertight.

HYDRAULIC MEASUREMENTS

17. Measurement of Water Level

Non-recording instruments. Simplest is a graduated GAGE BOARD, or piece of sa level rod, fastened to side of tank or reservoir, and read where water level cuts the It can be read to 0.005 to 0.01 ft. If the water surface is rough, a STILL WELL (a box at the top and with a submerged opening in side) may be used and the gage placed i Fig 36 shows a variation from the ordinary form of gage board, the sloping lines allowi

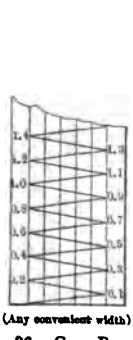

Fig 36. Gage Board

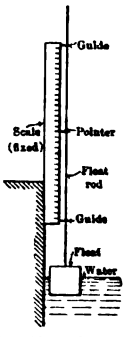

Fig 37. Float Gage

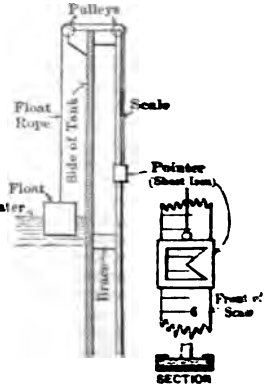

Fig 38. Float Gage for Tanks

more accurate estimate of water level. This design may be scratched with a nail side of a concrete tank before the concrete is fully set, or made by saw-cuts ⅛ in deep board. Fig 37 shows a more accurate instrument, a FLOAT GAGE consisting of a fixed and a pointer attached to a vertical rod on a float. As the reading is made on the this gage is convenient where the water surface is hard to reach. If a leveling rod

e scale, and a target vernier attached to the float rod, readings may be made to 0.001 02 ft. Fig 38 shows a float gage for a tank. By the HOOK GAGE a skilled observer can detect variations in water level of 0.0002 or 0.0003 ft. But such accuracy is seldom needed except in laboratory experimental work.

Recording gages. Fig 39 shows a simple form, which can be made by a good mechanic. The clockwork consists of an 8-day clock, with gearing to produce a revolution of the drum in any desired time. For recording weir flow, the vertical scale on the drum may be graduated to read discharge directly (Fig 13). Similar instruments, costing $75 to $150, are made by Hydro M'f'g Co, Phila, Pa; J. Friez, Baltimore, Md, and others. Fig 40 shows another recording gage. A drum *a*, containing a

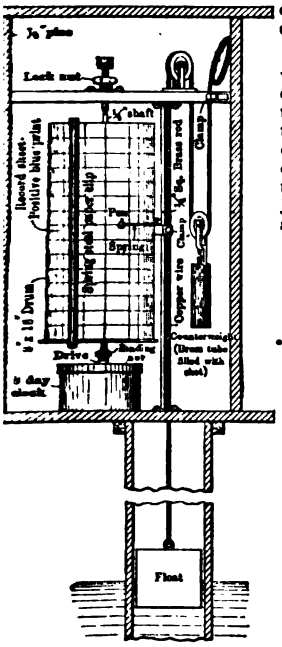

FIG 39. Recording Gage

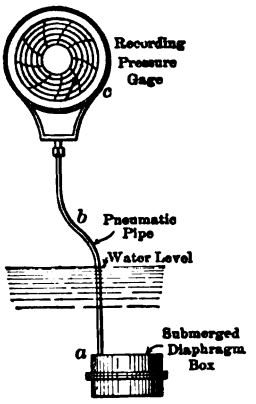

FIG 40. Bristol Recording Gage

diaphragm, is submerged in the water. Variation in water level causes variation in e of air in the drum, which is communicated by tube *b* to the recording gage *c*. ge is not interfered with by floating matter in the water, nor by ice, and is said r variations in level of ⅛ in (Bristol Co, Waterbury, Conn).

18. Measurement of Head or Pressure

lerate water press in tanks or pipes is generally measured ss tube or PIEZOMETER; higher press, by hydraulic gage, to Bourdon steam gage.

ead of a few ft a WATER TUBE is convenient, consisting of a tube attached to an opening in the pipe or tank, and having tube at its upper end. The tube is raised or lowered until the vel shows in the glass tube, and the distance of this level he datum (as center of pipe or bottom of tank) gives the head. ning in the pipe should be on a straight length of pipe, at right o its axis, and should have a sharp inner edge. The MERCURY TER (Fig 41) conveniently measures heads as high as 40 to ercury having a sp gr of 13.6. The distance *z* between the levels in the U tube, as read on the scale, is roughly 1/13 the actual head. True uals ($z \times$ sp gr of mercury) $+ z$.

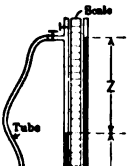

Fig 41. Mercury Piezometer

Hydraulic gages measure pressures up to 1 000 lb per sq in or 2 300 ft. **measuring DIFFERENCES IN PRESSURE** (if the press is very high) 2 gages are u

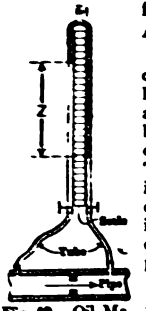

Fig 42. Oil Manometer

for very small differences, an **OIL MANOMETER** (Fig 42) (*T* A S C E, Vol 47, p 72) is used.

Kerosene oil is good. Its sp gr (which must be determined) is a 0.79. Hence the scale reading will be greater than the differen head, which is independent of height of o point of the scale above da and equals $z \times (1 - \text{sp gr of the oil})$. There may be trouble in obtaining good readings at the junction of water and oil, due to oil adhering to sides of tube. The **WATER OR AIR MANOMETER**, made by tube similar to that of Fig 42, can be used for small differences in head. Air must be pumped into the tube if the press is high. The reading is the true difference in head. Two open tubes could be used if total press is small.

Mercury manometer (Fig 43) is probably the best device for work of this kind. The true difference in head $= z \times (\text{sp gr of mercury} - 1)$.

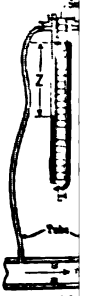

Fig 43. Me Manomet

In all these devices the length of tubes and the quantities of liquid used must be varied to suit the difference in head to be measured.

19. Measurement of Velocity and Discharge

For measuring small quantities it is best to allow the discharge for a given time to collect in a tank, where it may be measured or weighed. When this can not be done, or a permanent device is required, one of the following me must be used. Sometimes drop in hydraulic gradient can be measured, and discharge puted as in Art 11, but such results are liable to error due to uncertainty in value of the

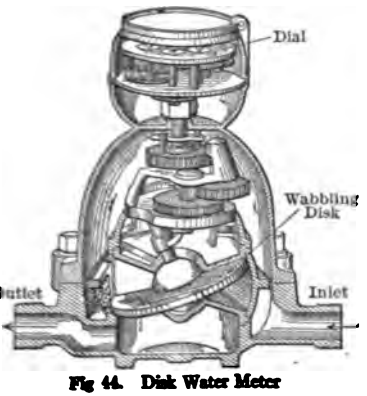

Fig 44. Disk Water Meter

Measurements in pres pipes. There are 3 method measuring water supply in o 2-in pipes, **DISK OR RING W METERS** are to be had in patterns.

The meter contains a wabbl or ring, so arranged that its mo communicated to a pin which works a train of clock wheels, the tity passing being registered on (Fig 44). This meter is "inferr and must be rated to determin discharge. Piston and other for meter are also used. All give ably accurate registration for ve flows (within say 10% for 10 g hr), but their rating varies wit and condition of meter and qual water.

Venturi meter is standard for permanent installations on pipes 3 or 4-i and over. They have been placed on the Catskill aqueduct for New Y water supply, pipe diam being about 14 ft. The meter consists simp gradual reduction in size of pipe to a throat ½ to ⅓ that of the pipe diam gradual expansion back to normal size (Fig 45). There is no obstruction flow of the water, and no moving parts.

Formula for discharge is based on the proposition that $h_1 + v_1^2 + 2g = h_2 + 2g$, and that $q = a_1v_1 = a_2v_2$. This gives $q = C \frac{a_1a_2}{\sqrt{a_1^2 - a_2^2}} \sqrt{2g(h_1 - h_2)}$, wh

a_2 = areas and h_1 and h_2 = pressure heads at the pipe and throat; g = acceleration
avity and C is a coefficient to allow for friction losses (usually taken at 0.99). A
meter is generally used to
ure $(h_1 - h_2)$, and for any
the formula reduces to $q =$
where z is the difference in
meter readings. (This meter

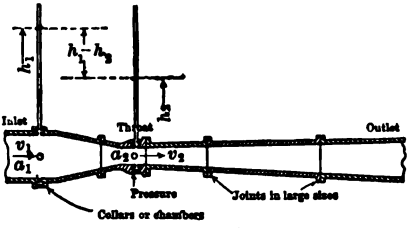

Fig 45. Venturi Meter

ot tube (1750) has been used in recent years. Fig 46 shows its principle.
urrent of water acting on the end of the curved tube causes the head in tube A to be greater than that in tube B. B measures pressure head only, and considering tube A to be a simple velocity-head proposition and the difference in levels equal to h, then $v = m\sqrt{2gh}$, where m theoretically = 1. If the action of the current against the tube is considered as impact, then $m = 0.7$. It has been shown also that, when placed so as to be subject to 2 currents of different velocities, the head is not that due to their mean, but to the mean of their squares. For high velocities, as in nozzles, m may be taken as 1 with quite accurate results. For pipes, in which velocities are low and vary as 48, the value of m is less, and for accuracy must be lined by ratings in a pipe of same diam.

Pitot Diagram)

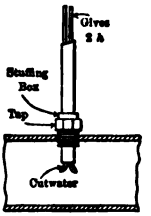

Fig 47. Pitot Tube

instrument is made by the Pitometer Co, N Y, who also make ling device. The usual form of Pitot tube (Fig 47) can be inserted in a hole tapped in a pipe, and a series of readings at different points in the diameter taken, from which the PIPE COEFF (Fig 48) is obtained. Knowing this, future measurements are made only at the center, center velocity being reduced to the mean by using the coeff. The makers advise using m =0.84.

e coeff $= \frac{\text{mean veloc}}{\text{center veloc}}$
$= \frac{1.97}{2.25} = 87.5\%$.

Measuring flow in open channels. The most accurate device is the (Art 10). Reliable data for weirs are available for a discharge up to about cu ft per sec. For greater discharge value, which is usually higher than limit of economy for the construction weirs, or where weirs are not warran or possible, floats and the current m are used. For floats a straight, uni section of the stream, at least 100 ft and on an even grade, should be sele Soundings are then taken, the stream divided into "lanes" like those in Fig If surface floats are used (small chip wood), a large number are allowed to down each "lane," and the time not the surface velocity of each course.

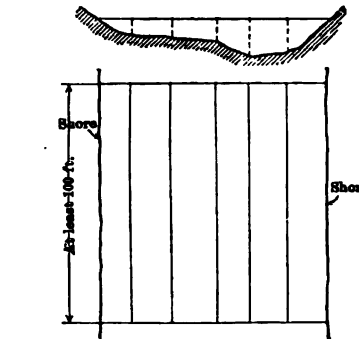

Fig 49. Soundings and "Lanes" for Measuring a Stream

Fig 50 shows variation in velocity in a tical section. To obtain the mean, the velocity must be multiplied by 0.79 to varying with roughness of bed and aver 0.86. Total discharge is found by multip the cross-sectional aver area of each lane by the mean velocity, and adding the re all the lanes. Wind affects surface floats, and shallow areas of dead water on the must be eliminated. A rough estimate of discharge can be made, with an uncertainty usually less than 20%, by timing floats down the center of a channel, thus obtaining the max surface velocity. Mean velocity in the entire cross-section is usually between 0.70 and 0.85 of this, the aver being 0.8.

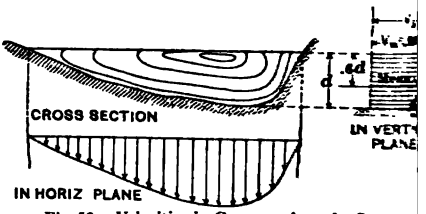

Fig 50. Velocities in Cross-section of a Stream

Submerged floats (Fig 51) are used particularly for deeper streams, and in studying tidal and other currents. By submerging the weighted float to a depth of about 0.6 (0.58 to 0.71) that of the vertical section which it floats, the mean velocity in the vertical is obtained.

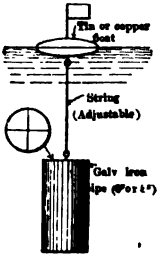

Fig 51. Submerged Float

Rod floats are hollow cylinders of tin, weighted by pebbles so as to stand vertically, and reaching nearly to the bottom channel. Francis gives $V_m = V_s (1.012 - 0.116 \sqrt{d'} + \ldots$ V_m = mean veloc in the vertical down which the rod floats, veloc V_s, d = total depth of stream, and d' = depth below S of rod. d' should not exceed 0.25 d. In practice it is difficult rod floats, as they require a very uniform channel, not obtainable except in canals and flumes.

Current meter is successfully used for measuring velocity and discharge in open channels and large pipes. It has four or more vanes mounted on a spindle, so arranged as to present always normal to direction of current, the pressure of which causes the vanes to revolve. The number of revolutions in a given time is recorded by an electric or mechanical counter, and is approx proportional to the current velocity.

The meter is first rated by moving it through still water at known velocities and noting the revolutions. If it is then submerged, by suspending it from a rod or rope, the re-

i can be counted and the velocity obtained from the rating chart. Usually the meter ld at a depth of 0.6 that of the water for obtaining mean velocity. It has been largely by the U S Geol Surv, for obtaining curves showing the discharge of a stream at rent elevations (stages) of water surface. Observers then note daily the water level, from the curves the flow is found. Two types of meter are in common use, the Price Fteley: the first for deep, rapid streams, the latter for shallow, slow streams (See Bib, "Use and Care of the Current Meter," *Trans* Am Soc C E, Vol 16, p 68).

liner's inch, as used in western U S, is the quantity of water which will in 1 min from a standard vertical orifice, 1 in sq, under a head at its center .5 in. This would equal 1.53 cu ft, but actual value varies in different dis-

s. In Cal and Mont, established by law 40 miner's inches = 1 per sec; in Col, 38.4, in Ariz, Idaho, Nev, Utah, 50 is accepted ommon agreement.

WATER SUPPLY

20. Estimates for Water Supply

sumption is stated in gal per capita per day. While there are many data avail- spect ing requirements for small towns and cities, showing variation from 30 or 40 or more gal per capita aver daily consumption, it is only recently that the subject eived much attention in mining communities; the scanty information existing is unsatisfactory, as such towns have been compelled to use what has been available than the quantity desirable. Frequently the supply for mills and power plants principal requirement.

rce of supply. Having estimated the quantity required, with allowance for future e of population, a source of supply is sought and developed. This will be either round water, springs or streams. The quantity available from underground water, ed by wells or infiltration galleries, can seldom be estimated except by performance s driven to the same strata. To make sure that a spring or stream will give suffi- upply, measurements of its flow covering a number of years are necessary. In case ams, which usually have large variation in flow, a storage reservoir may be possible. e up the flood flows to supplement the natural flow during dry seasons, thus furnish- arger supply throughout the year. (Art 21.)

n pipe lines. In designing these, it is necessary to allow for variations in consu inless the water is delivered to a small distributing reservoir, having a capa

sufficient to equalize variations. The main pipe may then be designed to furnish
to the reservoir at the aver daily rate. For domestic consumption, the max daily ra
generally about 150% of the daily aver, and max hourly rate 250% of daily aver.

Distributing pipes. The size is usually determined by fire service requirements
the system is to be used for fire service without engines, a pressure of about 30 lb per s
(70 ft head) is required at the hydrants, and for an adequate stream 150 to 250 gal per
should be supplied. Generally it should be possible to concentrate 2 or 3 streams on
one point without using hose over 400 to 600 ft long; these requirements fix the locat
of outlets and allowable loss of head in the pipes, and hence determine their size.

21. Rainfall, Stream Flow, and Storage

Water falling as rain passes off as surface flow into streams and rivers,
evaporated directly by the sun from the land surface, is taken up by plants
vegetation, or sinks into the ground forming ground storage, some of which fi
its way underground to the streams and furnishes their main supply at all ti
except during and just after storms. Thus, stream flow will vary in both t
amount and distribution throughout the year on two water-sheds having
the same rainfall, but different slopes, amounts of vegetation, depth, and ch
acter of soil cover. Hence, for accurate estimates, data on the flow of the str
in question are necessary. Such data are sometimes obtainable from the publi
tions of U S Geol Surv, state, city, and private reports, but in many cases
entirely lacking. It may then be possible to secure data from a similar wa
shed, bearing in mind what points constitute similarity or, it may be neces
to make a rough estimate from measurements of the slope and cross-sectio
the stream, at its known low-water mark, applying the formulas of Art 11
hydrograph, like that in Fig 53, gives a complete record of stream flow, and
be used for all kinds of estimates in connection with it.

For example, since a dam spillway should be designed to pass safely the flood flow sh
at F, the stream records should be searched for the greatest flood, and an estimate m
from high-water marks of the str
The vertical scale in Fig 53 is cu f
sec per sq mile, which, multiplied
the area of the drainage basin give
total flow. Area of the basin ca
obtained by drawing a divide lin
a topographic map, enclosing the
within which all rain falling
not lost by evaporation and seep
would drain off to the stream at
tion. This area may then be
off with a planimeter.

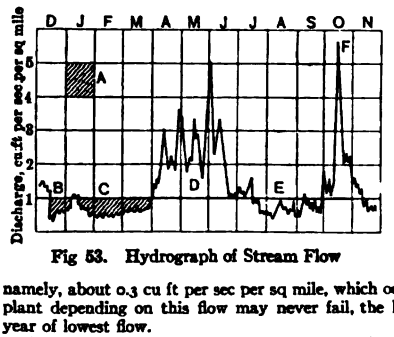

Fig 53. Hydrograph of Stream Flow

If no storage is available, the
flow to be counted on would be
minimum shown in the hydrogr
namely, about 0.3 cu ft per sec per sq mile, which occurs in December. In order that
plant depending on this flow may never fail, the hydrograph used must be that for
year of lowest flow.

If storage is available, the problem may be handled as follows. The area to be
hydrograph represents total flow for the year in cu ft, or the area A of 1 square inch
2 592 000 cu ft, which, divided by 43 560 = 5.95 acre ft, or a volume of 1 cu ft per
flowing for 1 month (30 days). For a flow of 1 cu ft per sec per sq mile, the re
storage will be the shaded areas B and C minus the small bit between them, where
hydrograph line rises above the 1-sec-ft line. This area can be taken off by planim
and changed to cu ft, giving the required storage. This storage is of course filled
the flow corresponding to D in the previous year, and will again be drawn down
although at E a smaller quantity is required than at B and C. If the storage is to
from a contour map of the reservoir site and assumed height of dam, and it is requir

he available flow, the problem is reversed and the line corresponding to the 1-sec- must be found by trial so as to enclose an area equal to the given storage.
: hydrograph shows that the distribution of flow throughout the year is very import- Streams fed by melting snows in mountainous regions show a much more even and r flow than in case of some southwestern rivers, which have little or no steady flow, re subject to violent and erratic floods caused by cloud bursts. In the former case, rsion dam may suffice for an adequate supply, or a small storage may be needed; in tter, a diversion dam must be built, and the flood flows, diverted to a reservoir or having a capacity sufficient to furnish the required supply for some months.
connection with storage reservoirs it should be noted that, as evaporation losses in egions are very large, it may be necessary to allow for 2 or 3 ft or more depth over ntire reservoir for this loss. Seepage losses also are sometimes very high, especially r the first 2 or 3 years following the completion of a reservoir. The total losses often nt to 25% of the influent, and under the best conditions are seldom less than 10%.

Introduction. The term thermodynamics has here been extended to include only part of the theory of the subject, but also formulas and numerical data on compression, steam, air and internal-combustion engines, fluid flow, combustion and related reactions. This section, therefore, is one of engineering, rather than of pu thermodynamics. In it reference is frequently made to Prof C. E. Lucke's work Engineering Thermodynamics (1). Methods of computing engine power, steam a fuel consumption, power to compress air and similar problems are given in Art leaving to Sec 40 the subjects of mechanical construction, sizes, costs and actual performance data of engines. Tables of physical and chemical constants frequent used in engineering computations are included in their respective articles.

1. Work and Power

Work in terms of pressure and volume. Work is expressed as the pro uct of force and distance; for the units of work see Sec 36, on Mechani Since pressure is force per unit area, following equations show that work is the product of press and vol:

$$PA = F, \quad \text{hence } W = PAL; \quad \text{but } AL = V, \quad \text{whence } W = PV,$$

ire P = press per unit area, A = area on which press acts, F = force acting, = work, L = distance, ft, and V = volume swept through while press is ng. The result is in ft-lb, if press is in lb per sq ft abs and vol is in cu ft.

iraphical representation of work. In Fig 1, the coordinates are press in er sq ft abs and vol in cu ft. Area denoting work done during any process nat under the curve, as AB, down to line of zero is; thus the work done during the volume change) B is the area $ABCD$.

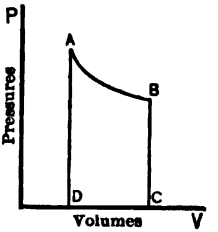

Fig 1. Graphical Representation of Work

Work of expansion or compression alone. When is changes in volume, work is done irrespective change in press; without change in volume, no k is done.

For constant press, $W = P(V_1 - V_2)$ (1)

" variable press, $W = P\,dV$ (2)

general expansion law for all gases is $PV^s = K$. n integrated, equation (2) assumes 2 forms, one n value of s in the general law is unity, the other n s has a value other than unity. Results of integration are given below veral convenient forms, in which P_1 is the greatest press and P_2 the least, eing the least vol and V_2 the greatest.

or special cases s has definite values for every gas. The most important case othermal expansion or compression, in which the temp is constant during expansion or compression, and $s = 1$ for all gases. Another important case is adiabatic compression or expansion, in which no heat is given to or removed from the gas during the process, and s equals specific heat at constant press divided by the specific heat at constant vol. Table 1 gives some adiabatic values of s, lying between 1 and 1.5.

$s = 1$	s not equal to 1
P_1V_1 Nap log $\frac{P_1}{P_2}$	$W = \frac{P_1V_1}{s-1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right]$ (3)
P_1V_1 Nap log $\frac{V_2}{V_1}$	$= \frac{P_1V_1}{s-1}\left[1 - \left(\frac{V_1}{V_2}\right)^{s-1}\right]$ (4)
P_2V_2 Nap log $\frac{P_1}{P_2}$	$= \frac{P_2V_2}{s-1}\left[\left(\frac{P_1}{P_2}\right)^{\frac{s-1}{s}} - 1\right]$ (5)
P_2V_2 Nap log $\frac{V_2}{V_1}$	$= \frac{P_2V_2}{s-1}\left[\left(\frac{V_2}{V_1}\right)^{s-1} - 1\right]$ (6)

pors may be assumed to behave as gases only when considerably superheated; when their saturation point, s is variable, and work determination by this method is in- . When steam expands so that it is just dry or follows the saturation law, $s =$ 5. For ordinary expansion of steam in a cylinder the average value of s is 1, but rpansion is not isothermal.

press in lb per sq in, L is length of stroke, ft, a is the net area of piston, sq in and n the number of cycles per min. The term nL is the PISTON SPEED, and $LAn \div 33\,000$, the ENGINE CONSTANT. Horsepower (hp) results from multiplying the constant by (m e p). Values for the constant are given in Table for different size cylinders and piston speeds. Piston speed is best obtained the product of number of working chambers, length of stroke and rev per min divided by number of revolutions to complete one cycle.

Example 4. What is the I H P of a 9 by 12-in single-cylinder, double-acting engine running at 300 rev per min, when the (m e p) is 50 lb per sq in? Diam of cylinder always the first dimension given when expressing size of an engine. In this case there are 2 working chambers, and a cycle is completed in 1 revolution; hence piston speed 600 and constant is 1.16, giving 58 I H P.

Example 5. What is the hp of a 6-cylinder, single-acting, 4-stroke cycle gas engine 6 by 6 in, running at 1 000 rev per min, if the (m e p) is 80 lb per sq in?

Piston speed $= (6 \times 0.5 \times 1\,000) \div 2 = 1\,500$; engine constant $= 1.29$; I H P $= 129 \times$

Brake or shaft hp, so called because it is found by a brake, is that actually available at the shaft or belt pulley, and equals the indicated minus the friction hp. Ratio of brake to indicated is the mechanical efficiency of the engine. In a combined machine, as a direct-connected air compressor or pump, the mech effic is usually taken as the ratio of the I H P of the air or water end to that of the steam end. But in a pump, the output is sometimes considered as the hp equivalent of the lb of water pumped $\times$ head pumped against.

Thermal efficiency is the ratio of work done in the engine cylinder to the work equivalent of the heat required to do it.

Example 6. A pump delivers 1 000 gal of water per min against a net head of 150 lb per sq in. The I H P of water end is 100 and of steam end 120, and it uses 75 lb steam per min, each lb containing 1 200 heat units. What are the mech and thermal effics? Considering the mech effic to be the ratio of work in the cylinders, there results $100 \div 120 = 0.833$ or 83.3%. Considering the output to be the net work of the pump, which $(1\,000 \times 8.3 \times 150 \times 2.31) \div 33\,000 = 87$, there results $87 \div 120 = 0.725$ or 72.5%. Work done per min in the steam cylinder is $33\,000 \times 120$, and the work equivalent of the steam is $778 \times 75 \times 1\,200$; hence thermal effic is 0.056 or 5.6%.

2. Flow of Gases and Vapors

Flow through nozzles and orifices, with large pressure drop. When gases or vapors expand in nozzles the expansion occurs so rapidly that there is no time for escape or addition of heat (although actually a portion of the energy of the jet is turned back into heat by friction against the nozzle walls), hence the process is assumed to be adiabatic, and the preceding equations apply as well in this case, called free expansion, as when the expansion occurs in a cylinder, called balanced expansion. As the fluid must be brought to the nozzle at that which has expanded must be removed, the complete cycle is as in Fig 3, the area $ABFE$ representing the work done by the fluid approaching the nozzle, area $BCDF$ that of expansion, and $CDEG$ that required to remove the expanded fluid at P_b, hence negative. Algebraic sum of these areas is

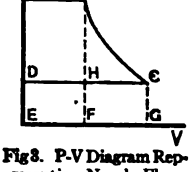

Fig 3. P-V Diagram Representing Nozzle Flow

$$W = \frac{s}{s-1} P_b V_b \left[1 - \left(\frac{P_c}{P_b} \right)^{\frac{s-1}{s}} \right]$$

If V_b represent the volume of 1 lb under the initial conditions, W is the work done by 1 lb, and if this work is used in accelerating the same 1 lb of fluid, then

$$W = (u_2^2 - u_1^2) \div 2g$$

nozzle work, w_1, the original velocity, is generally small as compared to w_2, final velocity, so that w_1^2 may be neglected; in which case, from Eq 9 and 10,

$$w_2 = 8.02 \sqrt{\frac{s}{s-1} P_b V_b \left[1 - \left(\frac{P_c}{P_b}\right)^{\frac{s-1}{s}}\right]} \qquad (11)$$

ight of fluid flowing through the nozzle follows directly, since it equals the duct of velocity, cross-section and wt per cu ft. Let A = area at point of imum velocity, then,

$$w = wA\delta_c = 8.02 A\delta_c \left\{\frac{s}{s-1} P_b V_b \left[1 - \left(\frac{P_c}{P_b}\right)^{\frac{s-1}{s}}\right]\right\}^{0.5}$$

re w = lb per sec, A = area in sq ft, and δ_c = wt of 1 cu ft at the low press. s generally more convenient to express δ_c in terms of original conditions since

$$\delta_c = \frac{1}{V_c} = \frac{1}{V_b}\left(\frac{P_c}{P_b}\right)^{\frac{1}{s}}$$

$$w = \frac{8.02 A}{V_b}\left(\frac{P_c}{P_b}\right)^{\frac{1}{s}} \left\{\frac{s}{s-1} P_b V_b \left[1 - \left(\frac{P_c}{P_b}\right)^{\frac{s-1}{s}}\right]\right\}^{0.5} \qquad (12)$$

ecomes a maximum when first differential = 0, which occurs when $\left(\frac{P_c}{P_b}\right)^{\frac{1-s}{s}}$ $= \frac{1}{2}$, or for the maximum flow,

$$P_c = P_b \left(\frac{2}{s+1}\right)^{\frac{s}{s-1}} \qquad (13)$$

ucing the lower press will not increase wt, but final velocity only. Throat of a nozzle is designed to pass the desired wt for the above press ratio, and mouth area to permit of the complete expansion. A relation between at and mouth area (by Moyer) is

$$\begin{aligned} \frac{\text{Mouth area}}{\text{Throat area}} &= 0.172 \frac{P_b}{P_c} + 0.7, \quad \text{if } \frac{P_b}{P_c} < 25 \\ &= 0.175 \left(\frac{P_b}{P_c}\right)^{0.94} + 0.7, \quad \text{if } \frac{P_b}{P_c} > 25 \end{aligned} \qquad (14)$$

line joining mouth and throat es greatly, but a common form is st a straight line and a 20° angle. he curve in Fig 4 shows the pressure $P_c \div P_b$ for max flow for differ- values of s. For all vapors, unless iderably superheated, s varies in e throughout the expansion, and e results for vapors by above od are not strictly accurate. For tact method see Art 10.

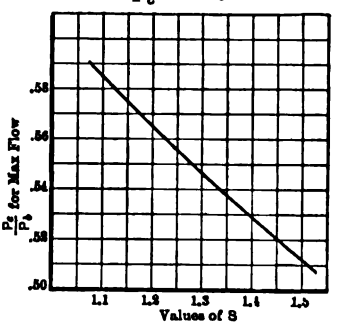

Fig 4. Pressure Ratio for Max Wt Discharged by Nozzle for any Value of "s"

he above equations are for perfect les or orifices, so that the actual lischarged, or the area to pass a n wt, may differ somewhat from calculated, due to stream contrac- For orifices with sharp corners effective area may be as low as 60% of the actual, while for nozzles it be as high as 95%.

For flow occurring when the low press is below the critical value the empir equations in Table 3 apply.

Table 3. Formulas for Flow of Steam and Air from Orifices

Lb dry steam per hr per sq in of orifice	$60\ p^{0.97}$	Grashof
	$51.43\ p$	Napier
	$49.6\ p$	Harter
	$[(10.57 - \log p)\ p] + 1\ 000$	Ratean
Lb superheated steam per hr per sq in of orifice	$60\ p^{0.97}$ [1 + 0.00065 × degrees of superheat]	Moyer
	$49.6\ p$ to $45\ p$ for superheat 0° to 185° at 160 lb	Harter
Lb of air per hr per sq in of orifice	$1\ 900\ p_1 + \sqrt{T_1}$ for flows from 2 atmos or more to 1 atmos	Fliegener
Lb of wet steam per hr per sq in of orifice	$60\ p^{0.97}$ + √dryness fraction	Grashof

Example 7. Calculate loss of air per hr from a tank in which the press is maintain at 90 lb per sq in gage and temp is 60° F, if there be a leak amounting to ⅛ in of effecti opening. Quantity of air escaping can be no greater than if the press without the ta were 53% of that within, so this value will be used for P_c in Eq 12. For conditi given, $V_b = 2$ cu ft; hence, by Eq 12, wt per hr =

$$3\ 600 \times \frac{8.02 \times 0.125}{144 \times 2} \times (0.53)^{0.71} \left\{ 3.5 \times 144 \times 105 \times 2\,[1 - (0.53)^{0.29}] \right\}^{0.5} = 1\ 07$$

By Fliegener's empiric equation the wt per hr = (1 900 × 105) + (520 × 8) = 1 99 Should the press within the tank be only 10 lb gage, the empiric formula would no long apply, since the low press is above the critical value, and the result must be found Eq 12. For above press, $V_b = 8.4$ cu ft, hence the wt per hr will be

$$3\ 600 \times \frac{8.02 \times 0.125}{144 \times 8.4} \times (0.6)^{0.71} \left\{ 3.5 \times 144 \times 25 \times 8.4\,[1 - (0.6)^{0.29}] \right\}^{0.5} = 253 \text{ lb.}$$

Flow through orifices with small press drops occurs in all engine a compressor valves, and in discharge from pipes. Use is made of this drop press for measurement purposes. For water and non-expansive fluids t velocity of flow is merely $\sqrt{2gh}$, but with expansive fluids the work done expanding must also be accounted for. In Fig 3, for a non-expansive fluid t work causing increase in velocity is represented by area *ABHD*, for expan fluids the area *ABCD*. Naturally, for small press differences the net work expansion *BCH* may be neglected. Hence, there are 2 sets of expressions f flow for small drops: (*a*) the exact, for expansive; (*b*) the exact, for non-e pansive and approximate for expansive.

$$\text{Lb per sec per sq ft of effective orifice} = \begin{cases} \sqrt{2g \dfrac{s}{s-1} \dfrac{P_1}{V_1} \left(\dfrac{P_2}{P_1}\right)^{\frac{2}{s}} - \left(\dfrac{P_2}{P_1}\right)^{\frac{s+1}{s}}} & \text{(a)} \\ \sqrt{2g \dfrac{P_1 - P_2}{V}} & \text{(b)} \end{cases} \quad (15)$$

where P_1 and P_2 are initial and final press, in lb per sq ft; V_1, the vol per lb a initial press; and V, the vol per lb at aver press, $(P_1 + P_2) \div 2$. The effect opening is always less than the actual; Table 4 gives values for the ratio effective to actual.

For air Eq (16) is useful, and Table 5 gives values for C found by Durley [6]. The values apply exactly for air flowing into a press of 30 in of mercury, between 40° and F, when the orifice is less than 1/10th the area of the approaching pipe or chamber, h sharp edges, and a thickness of 0.057 in. For a distance, they apply fairly well be

general, the constants for different s of orifice may be taken between limits shown in Table 6, no rule for ific cases being possible.

f the gas being measured is other a air the wt of flow is found from 17:

$$w_G = w_A\sqrt{V_A \div V_G} \qquad (17)$$

re w_G and w_A are the wt of gas and respectively, and V_G and V_A their per lb.

Table 6. General Limits of Constants (Weisbach)

Type of orifice	Constant
Rounded entrance	0.97–0.99
Sharp edge thin plate	0.55–0.80
Short straight tubes	0.80–0.85
" rounded entrance tube	0.92–0.93
Converging orifices	0.90–0.99

enturi tubes are used commercially for measuring gases and vapors, and e again 2 expressions result:

$$\text{Lb per sec} = A_2\left(\frac{P_2}{P_1}\right)^{\frac{1}{\delta}}\sqrt{2g\frac{s}{s-1}P_1\delta_1\frac{1-\left(\frac{P_2}{P_1}\right)^{\frac{\delta-1}{\delta}}}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{\delta}}}} \qquad (a)$$

$$= \frac{A_1}{\sqrt{A_1^2 - A_2^2}}\sqrt{2g(P_1 - P_2)\delta} \qquad (b) \qquad (18)$$

re A = area in sq ft, P = press in lb per sq ft, δ = wt per cu ft of gas, and ratio of specific heats, $C_p \div C_v$, of the gas. Subscript 1 refers to upstream,

and 2 to throat conditions, no subscript referring to the mean value. F steam the exact expression is simplified, since the factor

$$\frac{s}{s-1}\frac{P_1}{\delta_1}\left[1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] = 778 \times \text{work of Rankine cycle in B t u}$$

between pressures P_2 and P_1, and may be found by the Mollier diagram, Fig 2 hence,

$$\text{Lb steam per sec} = A_2\left(\frac{P_2}{P_1}\right)^{\frac{1}{s}}\delta_1\sqrt{\frac{2g \times 778\ (\text{work of Rankine cycle})}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{s}}}} \quad (1$$

Pitot tube is also used for measuring gases. As it is primarily a velocity meter sets of values are possible for its results, one neglecting the work of expansion, the oth accounting for it. But, to secure accurate readings the velocities must be high, so t the use of the exact expressions is more important than in the orifice or Venturi met As the readings are often in in of water or mercury, as well as in lb, the equations made to apply to these units also.

$$\left.\begin{aligned}\text{Lb per sec} &= A\sqrt{Z}\sqrt{2g\delta_1\left[1-\frac{K}{2s}\,\frac{1+s}{6s^2}K^2\right]-\left[\frac{(1+s)(1+2s)}{24s^3}\right]K^3} \quad (a)\\ &= A\sqrt{Z}\sqrt{2g\delta_1}\end{aligned}\right\}$$

$$\text{where } Z = P_2 - P_1 = 5.2\,(hw_2 - hw_1) = 70.8\,(hm_2 - hm_1) \qquad (b)$$

$K = \left(\frac{P_2}{P_1}-1\right)$, s = ratio of specific heats, $C_p \div C_v$, δ = lb per cu ft of fl

$(P_2 - P_1)$ = diff in press in lb per sq ft, $(hw_2 - hw_1)$ in in of water, and $(hm_2 - hm_1)$ i of mercury, subscript 1 referring to the tangential orifice and 2 to the impact orifice

Flow in pipes. For flow of gases and vapors through pipes there is lit more reliable information than empiric formulas, some of the commoner be given below (Gebhardt). For theory of pipe flow, see (1); for pipe sizes u in practice, see (5).

$$\text{Veloc, ft per sec} = A\sqrt{\frac{(p_1-p_2)d}{\delta L}}, \text{ where } A = \begin{cases}9\,240 \text{ Geipel \& Kilgour}\\ 9\,976 \text{ Hawksley}\\ 10\,350 \text{ Martin}\\ 10\,360 \text{ Hurst}\end{cases}$$

$$\text{Flow, lb per min} = B\sqrt{\frac{(p_1-p_2)\delta d^5}{L}}, \text{ where } B = \begin{cases}50.2 \text{ Geipel \& Kilgour}\\ 59.4 \text{ Hawksley}\\ 56.5 \text{ Martin}\\ 56.5 \text{ Hurst}\end{cases}$$

$$\left.\begin{matrix}\text{Press drop, lb}\\ \text{per sq in}\end{matrix}\right\} = C\frac{w^2L}{\delta d^5}, \qquad \text{where } C = \begin{cases}0.000396 \text{ Geipel \& Kilgour}\\ 0.000337 \text{ Hawksley}\\ 0.000313 \text{ Martin}\\ 0.000313 \text{ Hurst}\end{cases}$$

$$\text{Pipe diam, in} = D\sqrt[5]{\frac{w^2L}{(p_1-p_2)\delta}}, \text{ where } D = \begin{cases}0.2087 \text{ Geipel \& Kilgour}\\ 0.2010 \text{ Hawksley}\\ 0.1990 \text{ Martin}\\ 0.1990 \text{ Hurst}\end{cases}$$

In above equations. d = diam, in; $(p_1 - p_2)$ = press drop, lb per sq in; w = flow per min; L = length of pipe, ft, and δ = lb per cu ft of fluid.

Following values by Hunt show loss in press due to 90° elbows, expressed in equivalent ft of straight pipe.

Pipe, diam	Resistance	Pipe, diam	Resistance	Pipe, diam	Resistance	Pipe, diam	Resistance
1	1.5	5	20	9	44.4	16	90.1
2	4.9	6	25.9	10	50.7	18	104
3	9.4	7	32	12	63.7	20	117
4	14.5	8	38	14	76.7	22	130
....	.....	.....	.....	.....	.....	24	144

Draft due to convection flow, as found in chimneys and in some ventilating systems, depends on temp and height of stack or duct. For STATIC conditions difference in press of draft in in of water (the common unit) is $H\left(\frac{7.64}{T_C}-\frac{7.95}{T_H}\right)$ chimney gases, or $7.64\,H\left(\frac{1}{T_C}-\frac{1}{T_H}\right)$ for air. Due to flow conditions, wall stances, bends, changes of cross-sec in duct work, many of which can not be luated, the actual draft will be less. For chimneys the same is true, besides ch there are fuel-bed, boiler-tube and economizer resistances, rendering any empiric formulas of little practical value. Stirling suggests a corrected ation for actual draft:

$$\text{Actual draft, in water} = 7.64\,H\left(\frac{1}{T_C}-\frac{1}{T_H}\right)-\frac{fw^2CH}{A^3} \qquad (25)$$

re H = height, ft, T_C = abs temp of air, T_H = mean abs temp of hot gases, wt of gases per sec, C = perimeter of stack, A = area of stack, and f = a tant varying from 0.001 to 0.002, 3 values for which are: 0.001 for steel k (abs temp = 800), 0.0015 for steel stack (abs temp = 1 060) and 0.002 brick stack (abs temp = 760).

ndency of heated liquids and gases to rise is often utilized in heating or cooling ms to produce flow, the thermosyphon consisting merely of 2 pipes or flues, con- d at top and bottom; through one pipe the warmer, lighter fluid rises, through the r the cooler and heavier descends.

apacity of chimneys does not increase indefinitely with stack temp, but aximum when the temp is approx twice the abs outside temp. Formulas numerous and are all empiric. Chimney capacities are generally stated in r horsepower (B H P). Common formulas are:

$$\left.\begin{aligned} \text{B H P} &= 3.25\,A\sqrt{H}\ \text{(Christie)}\\ \text{B H P} &= 3.33\,E\sqrt{H}\ \text{(Kent)}\\ D &= 4.92\ (\text{B H P})^{3/8}\ \text{(Stirling)}\end{aligned}\right\} \qquad (26)$$

he last formula can also be stated as B H P = $12.6\,A^{3/4}$.

these formulas, A = area of top of chimney, sq ft; H = ht of chimney, ft; effective area, after deducting 4 in from diam or width, to allow for chimney ion; D = diam of chimney, in. The first 2 formulas include a function of nd therefore require previous determination of an H that will produce the t required to overcome the combined resistance of the full-bed, boiler, and

It is claimed that Stirling formula gives the stack area that costs least to truct, and that this area does not change with H, determined independently.

the coal burned and flue gas produced per B H P are indefinite, the formulas are ated below, giving capacity in lb of flue gas per hr; using in first formula 4 lb coal B H P (Christie); in second, 5 lb coal per B H P (Kent); in both formulas, 24 lb as per lb coal, and in the last, the Stirling value of 120 lb flue gas per B H P.

$$\left.\begin{aligned} \text{Lb flue gas per hr} &= 312\,A\sqrt{H}\ \text{(Christie)}\\ \text{“ “ “ “ “} &= 400\,E\sqrt{H}\ \text{(Kent)}\\ \text{“ “ “ “ “} &= 1\,508\,A^{3/4}\ \text{(Stirling)}\end{aligned}\right\} \qquad (27)$$

3. Work and Capacity of Air Compressors (See also Sec 15)

Isothermal compression requires the least work, but is impossible to a in practice even with the most efficient jacketing.

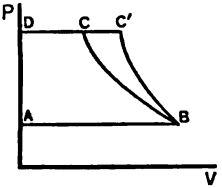

Fig 5. P-V Diagram for Ideal Single-stage Compression

Actual compressors operate with the compres line somewhere between isothermal and adiab Leakage of air from the cylinder during compre causes displacement of compression curve and giv lower value to exponent *s* (Art 1). Some compr diagrams show apparently isothermal compres whereas result is really due to leakage. Fig 5 sh an ideal diagram for the 2 cases in a no-clearan single-stage machine, area *ABCD* representing work for isothermal compression, *ABC'D* that adiabatic, and *CBC'* the saving due to the forma

Stage compression. Isothermal compression is more nearly approache the gas be compressed in one cylinder to some intermediate press, delivered t intercooler, and the compression completed in a second cylinder. This is ter staging, the number of stages being 2, 3, or 4, most commonly 2. Fig 6 shows the case for an ideal, no-clearance, two-stage machine. Area *ABCC'DE* represents the process as given, area *ABCD'E* that for single-stage adiabatic compression for same amount of air, and area *ABC'D''E* for single-stage isothermal compression. Saving due to staging is area *CC'DD'*.

The air is generally cooled to about the original temp in an intercooler, and in the following equations this assumption is made. The press to which the air is compressed, termed the RECEIVER PRESS, affects the saving due to staging. Maximum saving occurs in 2 stages when

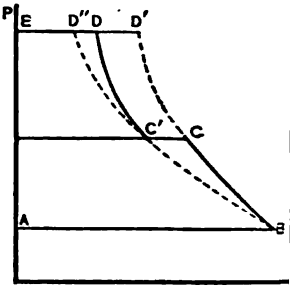

Fig 6. P-V Diagram for Ideal Tw stage Compression

$$\text{receiver press} = (\text{low press} \times \text{high press})^{.5}$$

and in 3 stages when

$$\text{first receiver press} = (\text{low press})^{.67} (\text{high press})^{.33}$$

$$\text{second receiver press} = (\text{low press})^{.33} (\text{high press})^{.67}$$

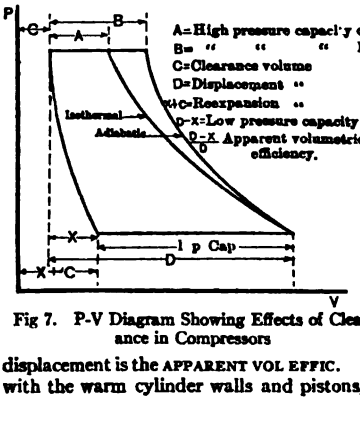

Fig 7. P-V Diagram Showing Effects of Clearance in Compressors

As real compressors have CLE ANCE vol, not all the air in th cylinder can be expelled on eac stroke, and the vol remaining m reëxpand to the low press bef any fresh air can be drawn i Hence, the quantity of air c pressed is always less than th piston displacement (Fig 7). Th ratio of the low-press capacity t displacement is the APPARENT VOL EFFIC. Since the entering air comes in contact with the warm cylinder walls and pistons, it expands, and hence the quantity

r drawn in, when measured under external conditions of press and temp, en less than would appear from the value of apparent vol effic. The ratio e actual vol drawn in to the cylinder displacement is the TRUE VOL EFFIC. o by Lucke is an attempt to formulate this quantity.

$$\text{rue vol effic} = \frac{\text{apparent vol effic}}{1 + (0.3 \text{ to } 0.5)\left(\frac{\text{abs temp air delivered}}{\text{abs temp air supplied}} - 1\right)} \qquad (30)$$

lelivered in other than isothermal compression is at a higher temp than supplied, and when cooled to original temp decreases in vol. Vol actually ered is termed the high-press capacity hot; when cooled, the high-press ity cold. These volumes for isothermal compression are equal.

pressions for work and capacity of single and 2-stage compressors are in Tables 7 and 8, in which following symbols are used:

low press, lb per sq in absolute
high press " " " "
receiver press, lb per sq in absolute
clearance, as a fraction of displacement
capacity, cu ft
diam of cylinder, in
stroke, in
cycles per min
displacement, cu ft per min

s = val of exponent of volume in equation for the compression curve $PV^s = K$, = 1.406 for adiabatic compression
T_1 = temp of entering air, abs
T_2 = temp of delivery air, abs
δ_1 = wt per cu ft of entering air
R_p = ratio, high press over low press
E_v = apparent vol effic
C_v = specific heat at constant volume
w = wt of air

scripts 1 and 2 refer to low and high-press cyl respectively.

ork required to compress a given quantity of air is endent of the clearance, but the size of the cyl- required varies with the clearance. A comparison e expressions for work for the entire single-stage ressor cycle and for compression alone (Eq 5) s that the work for the entire cycle is s times that ompression alone, that is, in Fig 8, area $ABCD$ imes area $BCEF$. Hence, Eq 7, if multiplied by es the complete work for adiabatic compression.

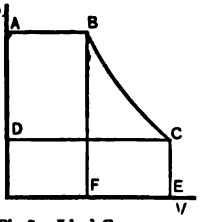

Fig 8. Ideal Compressor Card

ork of complete cycle for adiabatic compression
$$= JsC_v w\,(T_2 - T_1) \qquad (31)$$

se quantities of Tables 7 and 8 most frequently required may be found graphically Fig 9 to 11. Fig 9 is for finding the apparent vol effic for any clearance, press ratio, . Project from upper horiz scale to the proper curve for s, then horiz to the proper nce curve, and then down to lower horiz scale, where answer is read. By project-

om the s curve to left-hand scale the value of $R_p^{\frac{1}{2}}$ is found, which is useful in finde high-press cap hot, when the low-press cap or displacement is known, since

press cap hot = low-press cap $\div R_p^{\frac{1}{2}}$. Fig 10 is to find the work required to compress t, or the hp required to compress 1 000 cu ft of free air per min in one stage, between ressures and for any value of s. The upper of the 2 lower scales, when multiplied by ent vol effic, gives the m e p in lb per sq ft. To use, project downward from the value to the proper s curve, then horiz to the low-press curve, and finally downward to read nswer. Fig 11 is a diagram for 2-stage compression with best receiver press and ct intercooling. Results obtained by the expressions of Tables 7 and 8, or from the s, are for perfect compressors. The amount of saving by compressing in 2 stages single-stage adiabatic is seen in Fig 12. Here the horiz scale is the ratio of high to low, the vertical scale the ratio of the work required to compress a given amount in two stages to that required to compress an equal amount to the same pressure in

one stage. As the value of s effects the result, curves for various values of this are g on the figure. Knowing the press ratio, project from the value to the proper s cu and then horizontally the number so found when multiplied by the work required s stage will give that required for 2-stage.

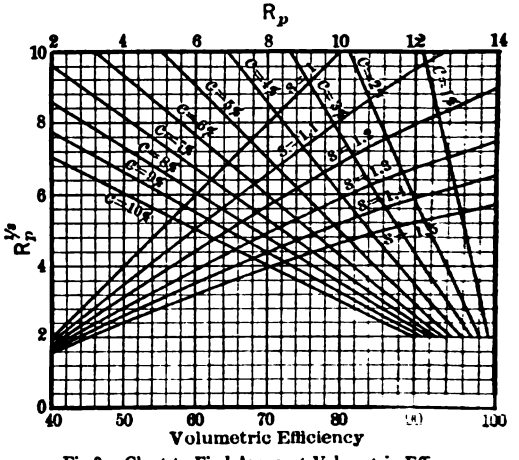

Fig 9. Chart to Find Apparent Volumetric Effic

Blowers are used for compressing large volumes of air or other gas to press below 1 lb. As the work to compress a given quantity of gas from one press to an is independent of the type of machine, all the above work formulas apply equa

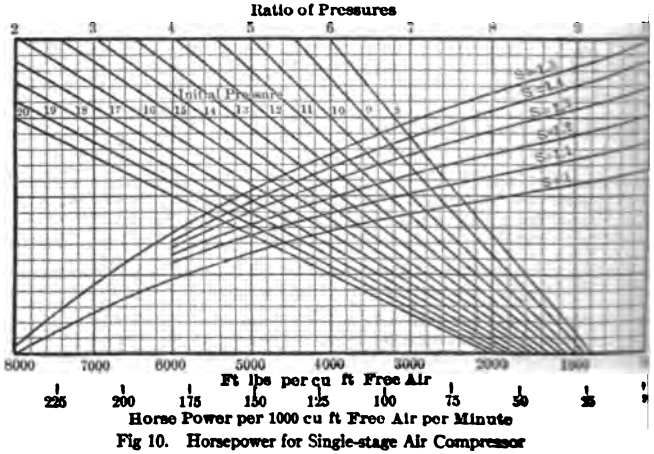

Fig 10. Horsepower for Single-stage Air Compressor

blowers. In case of fans the press to which the air is compressed is so little above of the atmosphere that the work of compression alone becomes negligible, so that work may be represented by the volume multiplied by the increase of press

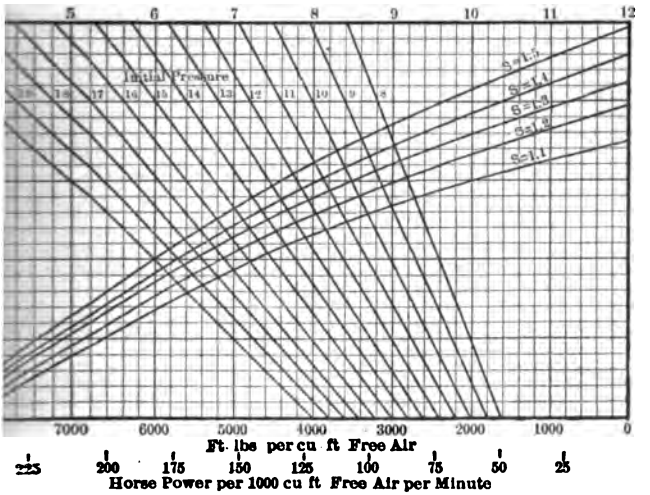
of press must include not only that actually observed, but also that required to ce the velocity with which the air leaves the fan or blower, or,

$$W = 144\,(p_s + p_v)\,Q \tag{32}$$



1. Horsepower for Two-stage Compression of Air, with Best Receiver Press and Perfect Intercooling

: Q = cu ft of air per min, p_s = increase of press, and p_v = velocity head, both in r sq in. Since

$$V = \frac{Q}{60\,A} \qquad p_v = \frac{\delta}{144 \times 2g}\left(\frac{Q}{60\,A}\right)^2, \quad \text{or,}$$

$$W = 144\,Q\left[p_s + \frac{\delta}{144 \times 2g}\left(\frac{Q}{60\,A}\right)^2\right] \tag{33}$$

ich δ = wt per cu ft of gas, and A = area of discharge opening, sq ft.

ıe above equations and es are for the ideal or per- nachine. Actual machines ire greater hp, to allow for ional and other losses. Re- n between the ideal and hp, termed the DIAGRAM OR, varies from 0.5 to 0.85; is, the power actually re- d in average practice will rom 2 to 1.2 that calcu- l for isothermal compres-

For further data on the pression of air, see Sec 15.

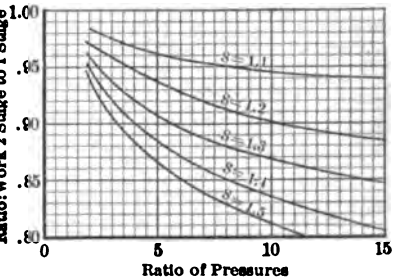


Fig 12. Diagram Showing Saving in Two-stage Air Compression

xample 8. What cylinder dis- ment per min and hp are required to compress adiabatically 1 200 cu ft of air from s press to 60 lb gage, in single-stage compressors, cylinder having 3% clearance?

From Table 7 the apparent vol effic is $1 + 0.03 - (0.03 \times 5) = 94\%$. Assuming inlet air to be at 60° F, the real effic (Eq 30) is

$$\frac{0.94}{1 + 0.4[1.58 - 1]} = 76\%.$$

The displacement per min will be 1 580 cu ft, and the work

$$144 \times 3.5 \times 1\,200[5^{0.29} - 1] = 110 \text{ hp}.$$

Similar results are obtainable from Fig 9, 10.

Example 9. What are the high and low-press capacities of a 2-stage compressor, and 17 by 12 in cyl, speed 120 rev per min, with 3% clearance in low-press cyl, operating at best receiver press and perfect intercooling? Compression is to 9 atmos abs. What power is required and how does it compare with that for a single-stage machine?

From Eq 28, receiver press = $(15 \times 135)^{\frac{1}{2}} = 45$ lb; hence, low-press apparent effic is $1 + 0.03 - (0.03 \times 3) = 96.5\%$. Assuming an initial temp of 60° F, the real effic (Eq 30) is $0.965 \div [1 + 0.4(1.36 - 1)] = 85\%$. Low-press capacity will be 85% of displacement, or 323 cu ft. High-press capacity hot (Table 8) is $323 \times (\frac{1}{3})^{0.78}$, or 43 cu ft; the high-press capacity cold being $323 \div 9$, or 36 cu ft. Power required for an ideal compressor is (Table 8 or Fig 11) 53.6, and from Fig 12 is seen to be about 84% of that for compression in one stage.

4. Power, Fuel Consumption and Thermal Efficiency of Piston Steam and Air Engines

Simple engines are those in which the fluid does work on the piston, and is then exhausted to the atmos or to a condenser. The fluid may be admitted for the entire stroke, or may be cut off at some point in the stroke and then expanded. Similarly, the exhaust may be for an entire stroke, or for only a part, followed by compression. Fig 13 shows the series of operations forming a cycle, for which 2 strokes are required. When the fluid is admitted to one end of cylinder only, the engine is single-acting; if to both ends, double-acting. Referring to Fig 13: A = admission, inlet valve opens; B = cutoff, inlet valve closes; C = release, exhaust valve opens; D = compression, exhaust valve closes; A–A' = admission at constant vol; A'–B admission at constant press; B–C = expansion; C–C' = exhaust at constant vol; C'–D = exhaust at constant press.

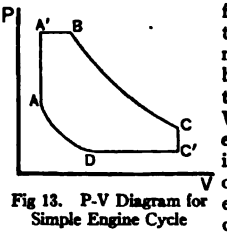

Fig 13. P-V Diagram for Simple Engine Cycle

Expansion curve BC may be of any form, but in steam practice it is a hyperbolic curve, so that $PV = K$; for air, it is usually assumed to be adiabatic, so that $PV^{1.41} = K$. Two sets of expressions are given in Table 9, one for

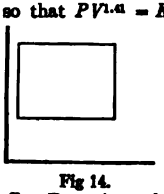

Fig 14. Zero Expansion and Compression

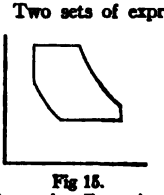

Fig 15. Incomplete Expansion and Compression

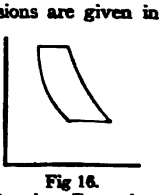

Fig 16. Complete Expansion and Compression

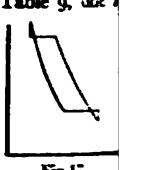

Fig 17. Over Expansion and Compression

$PV = K$, the other a general one for $PV^s = K$, where s may have any value other than 1. Four degrees of expansion and compression may exist (Figs 14, 15, 16, 17). In complete expansion the fluid expands in the cyl to the exact press of the exhaust, in incomplete expansion it fails to reach exhaust pres-

in over expansion it falls below it. Similarly, for complete compression the n trapped in the cyl at the end of exhaust is compressed to the initial press.

dicated horsepower (i h p) of an engine is given by the expression + 33 000, where p is the mean effective press (m e p)$_i$ lb per sq in, L the h of stroke, ft, a the net area of piston of piston minus area of rod, if there be sq in, n number of cycles per min. The tity LAn + 33 000 is the ENGINE CONSTANT Table 2 and its explanation).

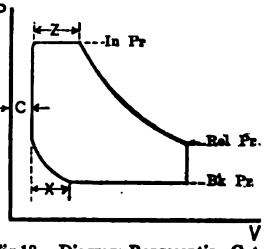

Fig 18. Diagram Representing Cut-off, Compression, and Pressures in Steam Engine Cycle

nsumption of engines is expressed in , or in lb of high-press fluid per hp hr, the r value being termed the WATER RATE. he equations, the letters have following nations: Z = cutoff = fraction of stroke leted when inlet valve closes; X = com-ion = fraction of stroke remaining when ust valve closes; c = clearance expressed fraction of the stroke; δ_1 = wt of a cu ft uid at the high press, as found from steam tables; (in pr), (bk pr), and (rel initial, exhaust, and release press, in lb per sq in abs (Fig 18).

$Z=(1+c)\frac{\text{bk pr}}{\text{in pr}}-c$	$Z=(1+c)\left(\frac{\text{bk pr}}{\text{in pr}}\right)^{\frac{1}{s}}-c$	(34)
$X=c\left(\frac{\text{in pr}}{\text{bk pr}}\right)-c$	$X=c\left(\frac{\text{in pr}}{\text{bk pr}}\right)^{\frac{1}{s}}-c$	(35)

iagram factor of an engine is the ratio of the m e p actually realized in the to that calculated as above. Actual m e p is always less, due to valve in-erence with steam flow and other causes. Values of diagram factors for erent types of engines are given under description of engines, averaging about to 0.7. SHAFT OR BRAKE HP of an engine is always less than the i h p, due friction losses. Ratio of brake hp to i h p is the MECHANICAL EFFICIENCY.

Actual consumption of engines is greater than the above values, du leakage past valves and from one side of piston to other, and to condensa of steam in the cyl. During exhaust stroke the cyl tends to cool down, s the temp of exhaust steam is relatively low. On admission of high-press ste some is condensed on striking the cooler cyl walls, allowing more to enter.

Missing water is the difference between actual and computed consumpt It is difficult to predict, as the condition of the engine (frequently unkno affects it greatly. Following empiric formulas (Perry) are in common use.

$$\text{For non-condensing engines, } R = m\,\frac{1+\frac{1}{Z}}{d\sqrt{N}}$$

$$\text{For condensing engines, } R = 120\,\frac{1+\frac{1}{Z}}{d\sqrt{ns}}$$

in which R is missing water divided by computed consumption, Z the ratio d the diam of cyl, in, N the rev per min, n the cycles per min, p the initial pre and m a constant varying from 5, in engines in very good condition and w jackets, to 30 or more in engines without jackets.

Multiple-expansion engines are those in which the steam, after do work in one cyl, is exhausted to one or more cyls and does more work by furth expansion. Amount of work which 1 cu ft of steam can do in expanding b tween initial and back press is independent of the number of cyls in wh expansion takes place, but a greater range of expansion can be had in a mul ple than in a single-cyl engine. This, together with a decrease in condensi and leakage losses, is the reason for employing compound and triple-exp sion engines. Should expansion occur in 2 stages, the engine is termed a co pound, a triple if in 3 stages, and quadruple if in 4. But, 2 cyls may be us instead of 1 large one for the lower press cyl, so that a compound is not nec sarily a 2-cyl, or a triple a 3-cyl engine. Exhaust from 1 cyl may be led direc to the next, or to an intermediate receiver. Should the fluid be heated betwe cyls, the receiver is a reheating receiver. It is considered good practice reheat air, but not steam. Since the size of receiver, arrangement of cran type of expansion curve, clearance, cutoff, and compression, in each cyl all ent into the expressions for m e p for multiple-expansion engines, these expressio become too complicated for presentation here (1). (See textbooks.)

Expressions for cu ft or lb of fluid consumed, as given for simple engines, may be us for multiple-expansion engines as follows: Z, X, c, and the pressures may be taken i either cyl and the m e p taken as referred to that cyl for which the values of Z, etc. a taken. The m e p referred to 1 cycle is a hypothetical m e p, which, if existing in a sim cyl of the same size as that to which it is referred, gives the same hp as the whole engi

$$\text{For compound engines: } \begin{cases} (\text{m e p}) \text{ ref to high press} = (\text{m e p})_H + (\text{m e p})_L \dfrac{D_L}{D_H} \\ (\text{m e p}) \text{ ref to low press} = (\text{m e p})_H \dfrac{D_H}{D_L} + (\text{m e p})_L \end{cases}$$

where D_H and D_L are the displacements of the high and low-press cyls.

Thermal effic of steam engines is the ratio of output to input. Redu ing both to 1 hp, this becomes thermal effic = 2 545 ÷ (water rate × H_1), in w H_1 is the heat content of 1 lb of steam above the feed-water temp, for value which see Art 12.

Thermal effic of air engines is generally considered as the work obtain from the engine for a given quantity of air, divided by the work to compr

ame quantity. Should there be preheating and reheating, the work-alent of the heat so supplied must be added to the work of compression. he work of engines, see above; for work of compressors, see Sec 15. Work-alent of the heat of preheat or reheat will be $778 w C_p (T_2 - T_1)$ where w of air, C_p = specific heat at constant press = 0.24 for air, and $(T_2 - T_1)$ umber of degrees through which the air is heated.

mple 10. Find the hp which a 15 by 18-in double-acting engine, with 5% clear-running at 200 rev per min, could probably furnish at the belt pulley for following ions. Initial press, 125 lb gage; back press, atmosphere; cutoff, ½; compression, What is the probable steam consumption? Taking s as 1 (as is general custom am work), from Table 9 the ideal m e p would be

$$140\left[0.05 + 0.55 \text{ Nap log } \frac{1.05}{0.55}\right] - 15\left[0.8 + 0.25 \text{ Nap log } \frac{0.25}{0.05}\right] = 102.$$

e a diagram factor of 80%, and a mech effic of 85%, as fair values. Then prob-i e p = 0.8 × 102 = 82.

piston speed = 2 × 200 × 1.5 = 600, hence from Table 2 hp constant is 3.21. h p will then be 3.21 × 82 = 263 and the b h p, 0.85 × 263 = 223. From Table indicated steam per i h p per hr is $\frac{13\,750}{82}\left[0.55 - 0.25 \times \frac{15}{140}\right] \times 0.31 = 27.5$ lb.

Eq 37 $R = \frac{30 \times (1+2)}{15\sqrt{200}} = 0.42$. The total steam per hr will then be 27.5 × 1.42 = 10 270 lb.

mple 11. If the engine in above problem be run for best economy, complete expan-nd compression must be had; hence (Eq 34, 35) $Z = 1.05 \times \frac{15}{140} - 0.05 = 0.062$ and $0.05 \times \frac{140}{15} - 0.05 = 0.42$. From Table 9, the ideal m e p is 21. Probable s then 46. The indicated consumption (Table 9) is $\frac{13\,750}{17}\left[0.112 - 0.47 \times \frac{15}{140}\right]$ 1 = 15.5, and R (Eq 37) is 2.4. Total steam per hr is 15.5 × 3.4 × 54 = 2 846 lb.

Power, Fuel Consumption and Thermal Efficiency of Internal Combustion Engines

these engines the heat is developed directly in the working cyl by burning el therein. Such engines may be divided into 2 classes; (*a*) those burn-e fuel at constant vol; (*b*) those at constant press. Fig 19 and 20 show the s on which they operate. Fig 19 s the Otto cycle, where

3 = adiabatic compression

0 shows the Diesel cycle, where

3 = adiabatic compression
) = " expansion
: = heating at constant pressure
l = cooling " " volume

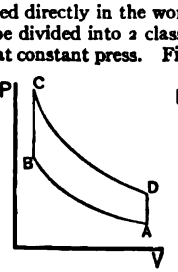

Fig 19. P-V Diagram of Otto Cycle

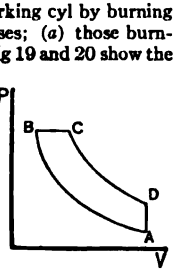

Fig 20. P-V Diagram of Diesel Cycle

ctually operated, both types draw in a new charge in each cycle, and expel roducts. These transfer phases may each take 1 stroke, or occur at the dead-r periods. In first case, the engine is a 4-cycle, in second, a 2-cycle, the 4 indicating the number of strokes per cycle. Expressions for m e p, thermal and fuel consumption, for Otto and Diesel cycles are given in Table 10.

Table 10. Expressions for m e p, Efficiency, and Fuel Consumption for (and Diesel Cycles

	Otto cycle	Diesel cycle
m e p.....	$\frac{JQ_1\left[1-\left(\frac{P_a}{P_b}\right)^{\frac{s-1}{s}}\right]}{144\,V_a\left[1-\left(\frac{P_a}{P_b}\right)^{\frac{1}{s}}\right]}$ or $5.4\frac{H_1}{s+1}\left[1-\left(\frac{P_a}{P_b}\right)^{\frac{s-1}{s}}\right]$	$\frac{J\left\{Q_1-C_vT_a\left[\left(1+\frac{Q_1}{C_pT_b}\right)^{s}-1\right.\right.}{144\,V_a\left[1-\left(\frac{P_a}{P_b}\right)^{\frac{1}{s}}\right]}$
Thermal efficiency..	$1-\left(\frac{P_a}{P_b}\right)^{\frac{s-1}{s}}$ or $1-\left(\frac{V_b}{V_a}\right)^{s-1}$ or $1-\frac{T_a}{T_b}$	$1-\frac{c_vT_a\left[\left(1+\frac{Q_1}{C_pT_b}\right)^{s}-1\right.}{Q_1}$
Fuel consumption per hr per i h p	$\frac{2\,545}{EH}$	$\frac{2\,545}{EH}$

J = Joule's equiv = 778; Q_1 = heat added per lb of working gases in cyl; P_a = pr at beginning of compression; P_b = press at end; V_a = vol per lb of air-gas mixture a ginning and V_b at end of compression; C_p and C_v = specific heats of gases at consta press and constant vol; H_1 = b t u per cu ft of gas or vapor; H = b t u per cu ft gas or per lb of oil; E = thermal effic, a = the air required to burn 1 cu ft gas or vap T_a = abs temp at beginning of compression; T_b = abs temp at end of compression.

Efficiency of Otto cycle depends only upon the degree of compression and is in pendent of amount of heat added. It may be expressed in terms of temp, vol or pre before and after compression, the latter being commonest. Table 11 gives values f efficiency for different compression ratios for the usual value of $s = 1.4$. Efficiency

Diesel cycle varies with the degree of compression, and with amount of heat ad In practice, efficiency is further decreased at heavy loads due to incomplete combus when large amounts of fuel are added. The m e p in each case is work divide change in volume. In above expressions, work is the product JQ_1E, and vol cha is expressed as a function of original vol. Heat liberated per cycle Q_1 divide vol of mixture admitted, or vol change, is the heat content per cu ft of mixtu

e. the m e p expression for Otto cycle may have the simpler form given in e 10. Table 12 gives the quantity $\frac{H_1}{a+1}$ or B t u per cu ft of air-fuel mixture for ommon fuels, at 32° F and 14.7 lb. For other conditions of press and temp, the s vary directly as the abs press and inversely as abs temp. Hence, solutions of prob- on the Otto cycle are chiefly a matter of finding tabular quantities. For solution e p by the other expressions, the heat liberated per lb of stuff in cyl must be known. idering Va to be the vol of 1 lb of mixture external to the cyl,

$$V_a\left[1-\left(\frac{P_a}{P_b}\right)^{\frac{1}{s}}\right]\frac{H_1}{a+1}=Q_1.$$

Table 12. Values of B t u per Cu Ft of Best Air and Gas Mixture

te. — Values at any other press and temp = values at 32° and 14.7 lb × $33.45\frac{p}{T}$, e p is press in lb per sq in and T is abs temp in deg F.

ble 11 gives values for $1-(P_a+P_b)^{\frac{1}{s}}$ and as the air-fuel mixture is largely air the er lb may be considered the same as air, values for which are given in Table 20. e fuel mixture external to engine is generally at atmos press and temp, an aver value is not greatly in error.

r liquid fuels the value for $\frac{H_1}{a+1}$ averages about 105, for city and natural 90, and producer gases 70. Values given for m e p and effic are all for perfect es. The diagram factor varies far more than for steam engines, but a rough e is 45 to 55%. Values for different types of engines are given in Sec 40.

ample 12. Find full-load hp, fuel consumption, and thermal effic of a single- g Otto 4-cycle 3-cyl 10 by 12-in engine, running at 500 rev per min, with a compres- press of 90 lb gage; fuel, alcohol. Compression ratio = (90 + 15) ÷ 15 = 7. Effic le 10) = $1-\left(\frac{1}{7}\right)^{\frac{s-1}{s}}$ = 0.427; or, from Table 11 = 0.427. Assuming diagram factor ; real effic = 0.21. Fuel per hp hr (Table 10), and value of 12 100 B t u per lb ol (Table 26) = 2 545 ÷ (0.21 × 12 100) = 1. This value is the probable consumption, the probable effic of 0.21 was used. Same result could be found by using the hypo- al value 0.427, and dividing by diagram factor 0.5. B t u per cu ft mixture, at o° F and atmos press (Table 12) = 95.5; hence m e p = 5.4 × 95.5 × 0.427 = 220 Applying same diagram factor, real m e p = 110. Piston speed = (3 × 500) ÷ 2 0. Hp constant from Table 2 = 1.785; hence, hp = 196.

ample 13. Find the m e p, fuel consumption, and thermal effic, of a single-cyl, le Diesel engine, operating on crude oil at full load. Compression ratio, 40. At etical full load in a Diesel there would be heat liberated due to best mixture, but lly there is always excess air. Assuming best mixture, Q_1 = 13 × 104 × 0.93 = , for temp of 60° F external to cyl. From the expressions following Eq 42, the temp equals the press ratio raised to $(s-1)\div s$ power, hence $T_b = 2.87 \times T_a$ = 1 500 abs;

$$\text{hence } E = 1-\frac{0.17\times 520\left(1+\frac{1\,250}{0.24\times 1\,500}\right)^{1.4}-1}{1\,250}=0.515$$

Assuming diagram factor of 0.5, real thermal effic becomes 26%. Fuel consumption assuming 19 000 B t u per lb oil, is 2 545 ÷ (0.26 × 19 000) = 0.51 lb.

M e p = (778 × 1 250 × 0.515) ÷ (144 × 0.3 × 0.93) = 290 lb.

Applying same diagram factor, real m e p = 145 lb.

6. Heat and Temperature Units

Thermometer scales in common use are Cent and Fahr, usually the la in American engineering practice. The fixed points on each are the freez and boiling points of water, at standard press of 760 mm of mercury. Fre ing point is denoted by 0° and 32°, boiling point, by 100° and 212°, on the C and Fahr scales respectively. 1° F = 5/9° C, or 1° C = 9/5° F. Temp F = temp C + 32, or temp C = 5/9 (temp F − 32). (See also Sec 37.)

Absolute temperature. Scales given above are purely arbitrary, and not be used in thermodynamic calculations for which abs temps are requir The more permanent gases, as air, hydrogen, oxygen, etc, or those much ab their condensation temp, when cooled at constant press, lose a definite amo in vol per degree of cooling. If cooled at constant vol, there is a definite crease in press of 1/273 per deg C, which is the same as the decrease in vol constant-press cooling. Considering a unit press or vol at 0° C, cooled thr 273°, there would be zero press if the cooling were at constant vol, or zero if cooling were at constant press. Temp of −273° C is therefore called abs zero Cent, and 0° on the same scale becomes 273° C abs. Similarly, 0 Fahr scale is 460° abs. The above values are in the nearest round numbe More exact values are:

0° C scale = 272.85° abs (Regnault)
0° F " = 459.64° " (Marks & Davis)

Units of heat. There are 2 units of heat, one corresponding to each of t above thermometer scales. That corresponding to the Cent scale, or met unit, is the calorie, or heat required to raise the temp of 1 kg of water fr 15° C to 16° C. This unit is sometimes called the large calorie, to distinguish it from the small calorie, which is the heat required to raise the temp of 1 g water an equal amount. The unit used in English-speaking countries is t British Thermal Unit (B t u), and is the heat required to raise the temp 1 lb water from 62° F to 63° F (Peabody) or 1/180 of the heat required to ra 1 lb of water from 32° F to 212° F (2). These values would be identical if the specific heat of water constant. The variation is slight, and for practi purposes the error arising from considering it constant and equal to unity ma be neglected. For detailed discussion of different values of specific heat water, see (2). 1 B t u = 0.252 calorie; 1 calorie = 3.968 B t u.

Mechanical equivalent of heat varies in different latitudes; a commo value in engineering work is 1 B t u = 778 ft lb (Table 13).

Table 13. Power Conversion Factors

Ft lb	B t u	Calorie	Hp sec	Hp min	Hp hr
1	1.26×10^{-3}	0.324×10^{-3}	1.818×10^{-6}	0.303×10^{-4}	5.05×10^{-7}

3.3×10^{4}	43.44	10.70	60	1	1.67×10^{-2}
1.98×10^{6}	2.545	641	3 600	60	1

7. Specific Heats

hen substances are so heated that no change of state occurs, as from solid iquid or liquid to vapor, and no heat is conducted away, the temp rises. ntity of heat required to cause temp of equal weights of different substances ise the same number of degrees varies. The standard is the heat required aise 1 lb water 1° F. Ratio of the heat required to raise 1 lb of a substance to that required to raise 1 lb water 1° F is its SPECIFIC HEAT.

eat may be applied to a substance at constant press or at constant volume. irst case the vol changes, and hence work is done; in second case no work lts. As work is done at the expense of heat, more is required to cause a n temp rise in the case of constant-press heating. Hence, there are 2 ific-heat values, C_p for constant press, and C_v for constant vol conditions. , in case of solids and liquids, the change in volume is so small as to be neg- le in engineering work, hence for these substances only one value is reported. ific heats of substances are not constant over the entire range of temps, have the form of equation, $C = a + bt + ct^2$, where a, b, and c are constants. he values of b and c are not definitely determined, and expressions involving ific heats become very complicated when the variable values are used, it is omary to use the constant values and apply correction factors where neces- at end of the calculation. See Tables 14, 15, 16.

1. Wiedeman. 2. Regnault. 3. Holborn-Austin. All values for C_v from (1)

For a mixture of substances the specific heat may be found by Eq 39:

$$\text{sp ht of mixture} = \frac{c_1w_1 + c_2w_2 + c_3w_3}{w_1 + w_2 + w_3}$$

where c_1, c_2, etc, are the specific heats and w_1, w_2, etc, the weights of the components. Equation 40 (Dulong and Petit) is useful where no experimental values are available:

$$\text{Specific heat of solids} = 6.4 \times \text{atomic weight}$$

Quantity of heat absorbed by or removed from a body on heating or cooling is given by $H = Cw\,(t_2 - t_1)$, where H = heat, w = wt, C = specific heat, and t_2 and t_1 temps

8. Coefficients of Expansion

Substances may be heated at constant vol or at constant press, but the change in vol of liquids and solids when heated at constant press is very small and is usually expressed in the form of a coefficient or change per deg. Solids may undergo both linear and volumetric change, the latter being substantially 3 times the former. Liquids are subject to volumetric expansion only. All gases have substantially the same coef over a wide range, which is $\frac{1}{460}$ of the vol at 32° F and atmos press. A gas following this law exactly is termed a perfect gas. Most of the common gases follow the law closely enough for practical purposes, but vapors, being gases only when at temperatures considerably above their condensation points, follow it less closely, so that for them results are only approx. Tables 17 and 18 give the coef of expansion for common substances

9. Pressure, Volume, and Temperature Relations for Gases

For a perfect gas, $PV = wRT$ (41)

ere P = abs press, lb per sq ft; V = vol, cu ft; w = wt, lb; R = the gas nt = 778 $(C_p - C_v)$; T = abs temp, deg F.

When a gas expands, $P_1V_1^s = P_2V_2^s$ (42)

comparison with Eq 41 shows the following relations:

$$= \left(\frac{V_2}{V_1}\right)^s = \left(\frac{T_1}{T_2}\right)^{\frac{s}{s-1}}$$

$$= \left(\frac{P_2}{P_1}\right)^{\frac{1}{s}} = \left(\frac{T_2}{T_1}\right)^{\frac{1}{s-1}}$$

$$= \left(\frac{P_1}{P_2}\right)^{\frac{s-1}{s}} = \left(\frac{V_2}{V_1}\right)^{s-1}$$

elations are shown graph- in Fig 21, the vertical epresenting press ratios, ale at bottom vol ratios, ri: scale at top, temp ra- The curves denote values eft-hand group of curves ations between press and ght-hand, between press np. Thus, for air expand- n 7 atmos to 1 atmos, the tio = 7, final vol will be 4 riginal, and final abs temp 4 times original abs temp.

Diagram to Determine Change in Specific Vol, with Press and Temp

For non-saturated conditions, results sufficiently accurate for most purposes can be obtained by finding dew point from tables or curves (Sec 23, Fig 1), computed for standard atmos conditions.

Example 14. Find wt of 1 cu ft of air, saturated with moisture at 100° F; wt of the air alone for the same conditions; and wt of water per lb of air, for barom reading of 27 in of Hg. For 100° the vapor press is 0.946 lb per sq in, the total press at 27 in of Hg is 13.25 lb per sq in; hence, the partial press of air is $13.25 - 0.95 = 12.30$. Wt of vapor per cu ft (Table 21) is 0.0028 lb. Wt of air per cu ft is $1 + Z$, or $1 + \left(0.37 \times \frac{510}{12.3}\right) = 0.0653$, and total wt $= 0.0653 + 0.0028 = 0.0681$ lb. Water per lb air $= 0.0028 \times 15.3 = 0.0429$ lb.

Example 15. Consider the above problem for air 54% saturated. The dew point (Sec 23, Art 1) is 80° F. Vapor press is then 0.505 lb per sq in; hence, partial press of the air is $13.25 - 12.75$ lb; wt of vapor $= 0.0016$, wt of air $= 0.0676$, total wt $= 0.0016 + 0.0676 =$ lb. Water per lb of air $= 0.0016 \times 14.8 = 0.0215$ lb, by same method as in Ex 14.

10. Vapors

apor is a gas near its condensation temp, or the gaseous form of a sub- normally a liquid or solid. Any liquid will evaporate or give off vapor temp, but only while the press exerted by the vapor is less than a certain

value, different for each temp and each substance. On reaching this p evaporation ceases, but if the temp be increased evaporation again takes p until a new pressure value is attained. Thus, for a liquid and vapor toget fixing the temp fixes the vapor press, and the curve showing this relatio $P - T$ coordinates is called the vapor press-temp curve, or the vapor-tem curve, of the substance. Relation between press and temp may be expre by an equation.

The press referred to in this paragraph is the press of the vapor alone, and is inde dent of the presence of other gases. Thus, if water be placed in a vessel in which the an absolute vacuum, and the temp maintained at 170° F, the press will rise to 6 lb sq in. If, instead of having a vacuum in the vessel, it had been filled with dry a 170° F and 15 lb, and the water then added, the press would have risen to 21 lb = 15 the air pressure not influencing the water. Here, the values 6 and 15 are termed the tial pressures of the water vapor and air. Vapor in presence of its liquid can not ha temp other than that fixed by the press; under these conditions it is SATURATED. B removed from the liquid it may be heated to a temp greater than the saturated Vapor under these conditions is SUPERHEATED, and the amount of superheat is expre in deg above saturation temp.

Dalton's Law. When a space is filled with 2 or more gases, the press erted equals the sum of all the partial pressures, and the mixture behaves single gas. Ratio of any partial press or vol to that of the whole may be pressed as a function of the weights and gas constants as follows:

$$\frac{P_1}{P_m} = \frac{w_1 R_1}{w_m R_m}, \quad \text{and} \quad \frac{V_1}{V_m} = \frac{w_1 R_1}{w_m R_m}$$

where P = press, V = vol, w = wt, and R = gas constant, the subscript 1 referring single constituent and m to the mixture. If one constituent is a vapor, its partial p is limited by the temp, and, when the press is that corresponding to the temp, the s said to be saturated, since the maximum amount of vapor is present. Actually it is space that is saturated, as the presence of the gas does not affect the vapor, but customary though quite incorrect to say that the gas is saturated. For this case following relation holds true,

$$W_v + W_g = P_v M_v + P_g M_g$$

where W = wt, P = press, M = molecular wt, subscript v = vapor and g = gas. If gas contains less wt of vapor than corresponds to the saturated state, the ratio of actual to saturation is termed the relative humidity (Sec 23, Art 1). If a gas-vapor mixture which relative humidity is less than 100%, is cooled at constant press, the temp at wh moisture begins to condense (that is, when saturation occurs), is called the dew point

Two humidity problems are important, dealing with moisture in the atm and with preparation of liquid fuels for internal-combustion engines. T humidity of the air is found by the psychrometer (Sec 23, Art 1) (1). T problem of humidifying air with liquid fuels can not be treated briefly enou to be inserted here (15).

Sublimation is the process by which solids pass directly to the vapor state with the intervening state of liquid.

11. Fusion and Evaporation

In Art 7 it was stated that if substances were heated without change of s the heat was manifested by a change in temp. But, under continued hea solids and liquids finally reach temp at which fusion, or change from so liquid, and evaporation, or change from liquid to vapor, will occur. Dur either process, the temp is constant if the press be fixed, and the heat ad directly proportioned to the wt of substance changed. Quantity of hea required to fuse or evaporate 1 lb of a substance is the latent heat of fus vaporization, and is exactly equal to the quantity which must be remo cause the condensation or solidification of 1 lb of the substance. LATENT

APORIZATION varies considerably with change of press, but the heat of fusion actically constant. Any change in the latter is of little importance in en-

e 22. **Temperature and Latent Heat of Fusion** (From Smithsonian Tables)

gineering, as fusion or solidification in most cases takes place at atmos pr
For equations expressing the heats of fusion and vaporization in terms of
quantities and their derivation, see Bib (8). The temp and latent heat
fusion, and temp and latent heats of evaporation, at atmos press, for
substances are given in Tables 22 and 23.

12. Properties of Steam

Properties of dry saturated and superheated steam are given in Tables
25, abridged from (2). For discussion of sources of data, see the original ta

Table 24. Properties of Saturated Steam

(Condensed from Marks and Davis's Steam Tables and Diagrams, 1909, by permis
of the publishers, Longmans, Green & Co)

Dry saturated steam is steam having the temp due to its press, but containing no moisture; it is rarely found in practice, as commercially "dry" steam usually contains from 1 to 4% of water, or is superheated. Quality of steam is designated by the amount of dry steam present in 1 lb of actual steam mixture, or by the degrees of superheat; for example, 95% dry steam means steam and stuff containing 95% of steam and 5% of water, and 100° superheat means steam having a temp 100° above that due to the press. As the values in the saturated table are for 100% dry steam, made from water at 32° F, corrections must generally be applied first for quality and second for the original temp. Two methods are available, first to follow the procedure actually occurring in the boiler, and second, to correct the table values for the heat not added to the steam.

Example 16. Find the heat required to make 1 lb of steam at 100 lb abs press. dry, from feed water at 100° F. By first method there must first be added enough to raise water from 100° F to the boiling point at 100 lb. From the tables the heat of the liquid at 100° F is 68, and at 100 lb is 298, or a difference of 230. If the specific heat of water were unity throughout the entire range, this should be the same as the difference between the temp at 100 lb and 100° F, or 228. But, the resulting error is negligible for practical work, and hence the heat to raise the water to the boiling point from the water temp may be considered as equal to the temp difference. When water has been raised to boiling point, 95% is evaporated; therefore, to the heat necessary to heat water is added 0.95 of latent heat of evaporation, or in this case 0.95×888, hence total heat $230 + 0.95 \times 888 = 1074$. By the second method the total heat from tables is, for

Table 25. Properties of Superheated Steam

pec vol in cu ft per lb, h = total heat, from water at 32° F, in B t u per lb, s = entropy, m water at 32°. (Condensed from Marks and Davis's Steam Tables and Diagrams)

a, 1 186. But, there was already in feed water the heat necessary to raise it to 100° F 32° F, or 68 units; also, 5% of latent heat was not utilized, because only 95% of water vaporated; hence, actual total heat = 1 186 − 68 −(0.05 × 888) = 1 074, as be' the superheated condition, the correction for heat in the feed water only is req'

13. Combustion and Combustion H

The process of combustion is exothermic or heat liber
the rapid oxidation of practically only 2 chemical elem
free or in combination with each other. Few natural
elements in the free state; they are generally combine
ner. The formation of the compound took place with th
tion of heat, so that when the fuel is burned there is liber
of heat which would result from the burning of an equiv
C and H, but a greater or less quantity depending upon w
of the compound develops or absorbs heat. The HEAT OF C
heat of formation of the products less the heat of formation
engineering calculations, it is generally sufficiently exact to
bustion as equal to the heat of formation of products, inasm
work the heat of combustion of a fuel should be determi

When H burns the product is H_2O in the gaseous state, equal
originally present. Usually the products pass off at a temp gre
lower temp the vapor will condense to liquid, giving up 970 B t u
per lb of H. Hence, fuels containing H may have 2 heating v
when the products cool to less than 212°, and the LOW VALUE,
definite common exists as to which should be used, nor is it more
clear understanding between the parties interested. Generally,
for boiler and other open fires, and the low values for explo
values are usually obtained by the calorimeter.

Table 26 gives heating values per lb and per cu ft at 32° F and
substances, and for common liquid and gaseous fuels. The lat
but give a general idea of what may be expected from such fuels

Table 26. Heats of Combustion

leating value of a fuel. To compute it, the chemical analysis must be wn. The fractional quantity of each constituent is then multiplied by its ting value, and the sum of these products is the heating value of the fuel. lyses of solid and liquid fuels are reported in percentages by wt, gaseous s, by volume. Coals are reported in 2 ways: proximate and ultimate anal-, the former ascertaining moisture, volatile matter, fixed carbon and ash, latter the chemical constituents, C, H, S, O, and ash. As the character of volatile matter can not be determined, attempts to compute the calorific ıe of coals from proximate analysis are not very successful, the ultimate ses being generally used. Following formula, by Lucke, applies with fair ıracy over a rather wide range of coals:

$$Q = 14\,544\,C + 27\,000\,V\left[1 - \frac{1}{\frac{C}{V} + 0.5}\right] \qquad (46)$$

hich Q = B t u per lb, C = fractional wt of fixed carbon, V = fractional wt olatile matter. When ultimate analysis shows both O and H, it is assumed ; the O, and as much of the H as can chemically combine with it, exist as er, and hence only the remaining H is available as a heat producer. Fol-ing formula, proposed by Am Soc Mech Engs, is based on this assumption:

$$Q = 14\,600\,C + 62\,000\left(H - \frac{O}{8}\right) + 4\,000\,S \qquad (47)$$

hich Q = B t u per lb, and C, H, O, and S are the fractional wt of carbon, rogen, oxygen, and sulphur per lb of coal.

ample 17: The calorific value of a coal was 13 900 by calorimeter. Proximate ysis: moisture, 1.25; vol matter, 39.03; fixed C, 53.72; ash, 6.00. Ultimate analysis: 1.47; C, 87.57; N_2, 1.09; O_2, 2.87; S, 0; ash, 6.00. Calculated values would be:

) by Eq 46, $14\,544 \times 0.537 + 27\,000 \times 0.39\left[1 - \frac{1}{1.38 + 0.5}\right]$ = 12 750 B t u

) by Eq 47, $14\,600 \times 0.876 + 62\,000\left(0.0247 - \frac{0.0287}{8}\right)$ = 14 085 "

) by calculation from ultimate analysis,

$$14\,544 \times 0.876 + 60\,626\left(0.0247 - \frac{0.0287}{8}\right) = 14\,003 \text{ "}$$

erman and Kropff found that the heating value of oils is a function of density, and ced following expression, which is within 2 to 3% of the calorimetric values:

$$Q = 18\,650 + 40\,(Be' - 10) \qquad (48)$$

= deg on Beaumé hydrometric scale, the usual mode of reporting oils. Stanton Strong revised the constant in Eq 48 for gasolene, and Allen and Strong for kerosene:

$$\left.\begin{aligned} Q &= 18\,320 + 40\,(Be' - 10), \text{ for gasolene} \\ Q &= 18\,440 + 40\,(Be' - 10), \text{ for kerosene} \end{aligned}\right\} \qquad (49)$$

an error of less than 1% in all tests.

ample 18. Find heating value of the following gas high and low values:

CO	H_2	CH_4	C_2H_4	N_2	O_2	CO_2
7	38	40	3	8	2	4

ultiply quantity of each combustible con-ent by its heating value (see table). sults found are for 32° and 14.7 lb, since eating values for the constituents are for press and temp. For any other press and the value will be the above $\times$ 33.5 $\frac{p}{T}$, e p = press, lb per sq in abs, and T = abs F. At 70° F, the values are 576 and 527.

High value	Low value
7 × 338 = 24	7 × 338 = 24
38 × 341 = 122	38 × 292 = 111
40 × 1 060 = 424	40 × 960 = 384
3 × 1 700 = 51	3 × 1 595 = 48
621	567

Air needed for combustion is most readily computed from the equations representing the reactions. The quantity required in actual equations is that which is chemically necessary. But, in burning [illegible] the possible exception in the case of internal-combustion engines, [illegible] more air must be supplied completely to burn the fuel than is theoretically required. The difference between these amounts is termed the excess [illegible]

Chemical symbols indicate the amounts as well as the substance entering into reaction. Thus the equation, $CH_4 + 2\,O_2 = CO_2 + 2\,H_2O$, may be stated in various ways: (a) CH_4 (methane) combining with O forms CO_2 and water vapor; (b) 16 lb CH_4 combined with 64 lb O forms 44 lb CO_2 and 36 lb water vapor; (c) 1 cu ft CH_4 with 2 cu ft O forms 1 cu ft CO_2 and 2 cu ft water vapor. Thus, not only does a symbol name the substance, but also gives the wt and vol reacting, as each symbol represents 1 unit vol, or the molecular wt of the substance in any units. In equations the wt is taken in lb and the vol in cu ft. The molecular wt of any substance is the sum of the atomic wts of the elements forming it, taken as many times as the symbol indicates. CH_4, for example, being composed of 1 C (atomic wt, 12) and 4 H atoms (atomic wt, 1), has a molecular wt of $12 + (4 \times 1) = 16$, and the symbol CH_4 indicates 16 lb of methane. It should be noted that the molecule of simple gas is composed of 2 atoms, hence we write H_2, O_2, or N_2 to represent hydrogen, oxygen, or nitrogen, and not by H, O, or N. For the atomic weights of the elements, see Sec 37.

As air is approx 21% O by vol, or 23% by wt, the air required for complete combustion of a substance is found by dividing the vol of O required by 0.21, or the wt of O required by 0.23. Table 27 gives the air required per lb or cu ft of different substances.

Table 27. Air Chemically Required for Complete Combustion

Symbol	Substance	1 lb requires	
		cu ft	lb
C_2H_2	Acetylene	165.2	13.3

To find the air required by a mixture of substances, if its analysis is given by volume, add the quantities of air needed for each constituent. To find the wt of air required for solids and liquids, add the wts required for each constituent. To find the vol required for gases and vapors [illegible]

mple 19. Find the air required to combine chemically with 1 lb coal, the ultimate sis of which is given under Example 17:

By chemical equations:

$$H_2 + O = H_2O \qquad C + O_2 = CO_2$$
$$2 + 16 = 18 \qquad 12 + 32 = 44$$

1 lb H_2 requires 8 lb O_2, and 1 lb C requires 32 ÷ 12 lb O_2; therefore, the O required al per lb is

$$\left(0.0247 - \frac{0.0287}{8}\right) \times 8 + 0.8757 \times (32 \div 12) = 2.51 \text{ lb}$$

Se air required is 2.51 ÷ 0.23 = 10.9 lb. Should the vol be required, the wt may ultiplied by the cu ft per lb at the press and temp desired.

By Table 27,

$$\left(0.0247 - \frac{0.0287}{8}\right) \times 34.6 + (0.8757 \times 11.6) = 10.9 \text{ lb}$$

mple 20. Find the air required for chemical combination with a gas, the analysis ich is given under Example 18:

By chemical equations:

$$2H_2 + O = 2H_2O \quad CH_4 + 2O_2 = CO_2 + 2H_2O \quad C_2H_4 + 3O_2 = 2CO_2 + 2H_2O$$
$$0.5 = 1 \quad 1 + 0.5 = 1 \quad 1 + 2 = 1 + 2 \quad 1 + 3 = 2 + 2$$

1 cu ft H_2 or CO requires 0.5 cu ft O_2, 1 cu ft CH_4 requires 2 cu ft O_2, and 1 cu ft requires 3 cu ft O_2; therefore, the gas requires

$$(7 \times 0.5) + (0.38 \times 0.5) + (0.4 \times 2) + (0.03 \times 3) - (0.02 \times 1) = 1.095 \text{ cu ft } O_2,$$

he air needed = 1.095 ÷ 0.21 = 5.22 cu ft. To convert to lb, multiply by the y at the existing press and temp.

By Table 27,

$$(0.07 \times 2.39) + (0.38 \times 2.39) + (0.4 \times 9.59) + (0.03 \times 14.34) - (0.02 \times 4.8) = 5.22 \text{ cu ft.}$$

$$\text{Wt air per lb fuel} = 11.5\,C + 34.6\,H \text{ (approx)} \qquad (50)$$

e above expressions and methods are useful in finding the air chemically red. The actual quantity of air for combustion is found by analysis of lue gas. Then, the air required per lb of C is determined by Eq 51, for containing but little H; when there is much H, the relations are too com- to be of much use.

$$\text{Lb of air per lb } C = (3\,N_2 + 0.165\,O_2) + (CO + CO_2), \qquad (51)$$

N_2, O_2, CO, and CO_2 are percentages by vol by flue-gas analysis.

oducts formed by combustion are chiefly CO_2, water vapor, and the N the air. When excess air is used this is also found in the products. When ficient air is supplied, it is generally impossible to predict the analysis of roducts, because the quantity of the available air received by each com- ble can not be foretold.

mple 21. Compute the products of combustion for the fuels of Example 19 for ase of the necessary and of twice the necessary air. From the equations, 1 lb C s 44 ÷ 12 lb CO_2, and 1 lb H_2 makes 9 lb H_2O; hence, 9 × 0.0247 = 0.222 lb H_2O + 12) × 0.8757 = 3.21 lb CO_2 + 0.0109 lb N_2 from fuel, and 0.77 × 10.9 = 8.4 lb om air. With 100% excess air, the water vapor, CO_2, and N from the coal will be me, and the N from the air twice as great, and there will be 10.9 × 0.23 lb of O the excess air.

ss due to incomplete combustion of C to CO instead of CO_2 is found flue gas analysis by Eq 52:

$$\text{Loss due to unburned CO per lb C} = 10\,193\left(\frac{CO}{CO + CO_2}\right) \qquad (52)$$

Producer reactions. Gas producers produce a combustible gas from fuel, as coke, anthracite coal, and to a less extent from bituminous coa nite, etc. The nearer pure carbon the fuel, the better the result. If the ducer blast be air alone, the reactions are: $C + O = CO$, $C + O_2 = CO_2$, $CO_2 + C = 2\,CO$; if with steam alone, not a continuous process, the rea is $C + H_2O = CO + H_2$; or steam and air may be used together, in which the composition of the gas formed is too complex to discuss here (1).

Final temp and press due to combustion. Combustion may take at either constant press or constant vol, explosively or nonexplosively, in press being characteristic of explosive combustion, but not necessarily fining it. For explosive combustion a mixture of fuel and O, with or wit neutral gases, as N, must be present and intimately mixed, so that a once started proceeds rapidly throughout the mass.

A rise in temp always occurs, but which can only be estimated, because of uncertai of specific heats and other phenomena. Mode of procedure is to apply correction fac found by experience to the hypothetical results computed. Temp rise due to combusti

$$t_2 - t_1 = C\,\frac{Q}{17\,w}, \text{ for constant vol} \qquad (a)$$

$$t_2 - t_1 = C\,\frac{Q}{0.24\,w}, \text{ for constant press} \qquad (b)$$

where t_1 and t_2 are the initial and final temp, Q the heat liberated, w the wt of prod formed, and C a constant. Value of C lies between 0.45 and 0.55 for both furna bustion and gas-engine work, when there is about the chemically correct amount of a but it has higher values for excess air. The vol and press changes due to combustion

$$V_2 - V_1 = \frac{V_1}{T_1}\left(\frac{CQ}{0.24\,w}\right); \quad P_2 - P_1 = \frac{P_1}{T_1}\left(\frac{CQ}{0.17\,w}\right).$$

where V_1, P_1, T_1 are the original vol in cu ft, press in lb per sq ft, and temp in de V_2, P_2, T_2 the final values, Q the heat liberated, C the constant as above, and w t of products. The press rise is more conveniently expressed by

$$\text{Press rise, lb per sq in} = 72.3\,C\left(\frac{\text{initial press, lb per sq in abs}}{\text{initial temp, }^\circ\text{ F abs}}\right) \times \left(\begin{matrix}\text{B t u per cu ft of mixture}\\ \text{at } 32^\circ\text{ F \& } 14.7\text{ lb abs}\end{matrix}\right)$$

Temp of ignition is the temp to which a substance must be heated b combustion takes place. Experiments by Falk and others indicate that temp is not constant.

Falk proved that for gaseous mixtures, it varies with the proportion of gas to air. gives following values, as true over a 100% range of proportions.

Ignition temp of gasolene mixtures with air..... 986° F
" " " alcohol " " " ..... 1 292° F

Beyond certain limits of the air-gas ratio, mixtures will not ignite. Table 28 gives this limit for several gases, expressed in terms of the percentage of detonating mixture which must be present for ignition to occur. By DETONATING MIXTURE is meant the combustible portion of fuel plus the O required for combustion.

Table 28. Percentage of Detonating Mixture in Total Air-gas Mixture at Explosive Limits of Proportion (Bunte)

e **of combustion** of coal is controlled by the draft. Following rela-) holds for small-size anthracite and bituminous coal.

$$\text{Lb coal per sq ft grate surface per hr} = C\sqrt{\text{Draft, in of } H_2O} \qquad (56)$$

ere C has the following values: Anthracite rice, 17.3; anthracite No 1 heat, 24.5; anthracite pea, 31.5; semi-bituminous, 50.2; bituminous, run- e, 81.6; bituminous, slack, 59.3.

ciency of combustion in furnaces is the ratio of heat developed to that ned in the coal; sometimes termed furnace effic, and ranges from 80 to In producers, the effic is a matter of gasification, and is the ratio of the 1 the gas from 1 lb of coal to the heat originally in the coal.

14. Heat Transfer

ept in the burning of explosive mixtures, heat is practically never devel- n the substance heated. In all other cases, heat must be conducted or nitted to the desired point, generally through separating walls. Flow of ıay be grouped in 3 classes, internal conduction, radiation, and convection.

Internal conduction is the passage of heat along a bar of any subs from a hot to a cooler zone. In this case, the characteristics of different m rials are fairly well known.

Values for common substances are given in Table 29, in which K is the B t u mitted per hr through a plate 1 ft square and 1 in thick per deg difference in temp not constant, but varies with the temp in a linear relation; that is, $K_t = K_{32}[1 + a$ 32)]. Where value of a is known, it is given in Table 29; when not given, the s value found must be used regardless of temp. If the temp range be great, the value of the coeff must be used, the mean value of K between 2 points being

$$K_{32}\left(1 + \frac{a}{2}[(t_2 - 32) + (t_1 - 32)]\right);$$

hence the heat flow through a body by internal conduction is

$$Q = \frac{A}{l} K_{32}\left(1 + \frac{a}{2}[(t_2 - 32) + (t_1 - 32)]\right)(t_2 - t_1),$$

where Q = B t u per hr, A = cross-sec of path in sq ft, l = length of path, in, K_{32} = c at 32° F, t_2 = high temp, t_1 = low temp. Temp t_2 and t_1 must be taken in the b itself; not in the fluid surrounding it.

Radiation of heat by a body is the transfer of heat from a hotter to a co body, without warming the intermediate space. Most common exampl the sun's heat, which warms the earth, but not the intervening medium. permeability of different materials to heat waves varies as with light waves. a substance easily passed by one is not necessarily passed by the other. most accepted law for heat radiation is that of Stefan and **Bolzman**; the h radiated from an incandescent body, black when cold, varies as the differe of the fourth powers of the temp, thus:

$$\text{B t u radiated per hr per sq ft} = 16 \times 10^{-13}(T_2^4 - T_1^4),$$

where T_2 = abs temp F of the radiating, and T_1 = that of the receiving, bod

Practically the only black body (that is, one which is 100% efficient in absorbing h rays and reflecting or transmitting none) is carbon, the crystalline form excepted other bodies reflect some heat and fail to radiate to the same extent. As radiatin creases with roughness and darkness, surfaces from which radiation is not desire frequently polished. Table 30 gives relative radiating and reflecting power of differ substances, compared to carbon as unity for radiation and zero for reflecting power course heat rays striking at an angle are partly reflected, and for small angles nearly the heat may be reflected.

Table 30. Radiation and Reflection Coefficients (Kent)

Substance	Radiating or absorbing power	Reflecting power	Substance	Radiating or absorbing power	Reflecting power
Brass cast	0.11	0.89	Ivory, Jet, Marble	0.93–0.98

Convection is the actual conveyance of heat by the movement of partic of a substance. The most important example is the heating of water in vessel

e the heat applied to the bottom is carried up through the liquid by the ties of water, which, on becoming warmer, grow less dense and tend to or rise through the mass being heated. Convection can occur only in ds or gases, substances in which the particles are free to move, and as tion and conduction generally take place at the same time it is difficult late the convection effect.

eat transfer between separated fluids. When heat flow passes from ody to another, a high resistance to flow is encountered, even a carefully- joint being equivalent to several inches of the bar itself. Hence, boiler s are not allowed in contact with the fire, because the high resistance of oint would prevent the carrying away of heat fast enough to prevent the ide from overheating. Between a plate and a fluid a film adheres to the , causing high resistance; by reducing this, agitation of the fluid or high ity increases the rate of heat transfer.

erally, in heat transfer apparatus, there is high resistance to flow on one side or ther of the separating wall, and but little improvement is realized by agitation or r effort on the low-resistance side. In boilers, for example, the high resistance lies en the gases and tubes, and effort spent on the water side avails little. The total ance to heat transfer is therefore made up of the resistance of the materials through the heat must pass, plus the joint resistances, plus the film resistances, of which the s of very few can be determined. Considering a boiler tube, the path is made up of r of soot and ash of unknown thickness and conductivity, a film resistance between ases and this, a joint resistance between the soot or ash and tube, the tube itself film resistance between tube and water. The practical solution of such a problem ys a coeff of heat transmission experimentally determined for various frequently- ring conditions, and including all the separate resistances and radiation and con- n effects. Such coeff, generally designated by U, expresses the B t u transmitted r per sq ft of surface per deg difference in temp, measured in the separated fluids, f which is receiving heat from the other. Values of U in aver practice are in Table The heat transmitted per hr is

$$Q = AUt_m, \tag{59}$$

: Q = B t u per hr, A = area in sq ft, U = coeff, t_m = mean temp difference between uids.

able 31. Coefficients of Heat Transfer U. Averages Used in Practice

Giving heat	Receiving heat		
	Liquid warming	Liquid boiling	Gas warming
uid cooling	50–75	{25–50 / 100*}	2–6
s cooling	2–5	2–5	2–5
or condensing	{150–350 / 1 000*}	400–600	2–4

* High liquid velocity or agitation.

ean temp difference is merely the difference between the hot and cold s, if throughout each the temp be constant. But, in most cases the temp of or both is changing in accordance with which one of the 4 possible cases n below is being considered:

bstance losing heat may be	Substance receiving heat may be·
) at constant temp	at constant temp
) " " "	rising in temp
) falling in temp	" " "
) " " "	at constant temp

Case (*c*) may occur for either parallel or counter-current flow; in the former both fluids enter at same end of the system, the final temps approaching the same value; in the latter, the fluids enter at opposite ends, final temp of one approaching initial of other. For cases where either or both fluids are changing in temp

$$\text{Mean temp difference} = \frac{\text{Initial temp difference} - \text{final temp difference}}{\text{Nap log}\left(\dfrac{\text{Initial temp difference}}{\text{Final temp difference}}\right)}$$

Example 22. A solution the specific heat of which is 1.2 is to be heated to 170° in a heater by 60° by exhaust steam at atmos press and 90% dry. Find the surface required to heat 50 000 lb per hr, also the steam needed, neglecting any heating by condensed steam.

$$\text{By Eq 60, } t_m = \frac{(212 - 60) - (212 - 170)}{\text{Nap log}\left(\dfrac{212 - 60}{212 - 170}\right)} = 86$$

$$Q = 50\,000 \times 1.2 \times 110 = 6\,600\,000 \text{ B t u}$$

$$\text{Heat per lb steam} = 970 \times 0.9 = 873, \text{ and lb steam} = \frac{6\,600\,000}{873} = 7\,550$$

$$\text{From Table 31, } U = 150 \text{ to } 350, \text{ say } 300, \text{ and from Eq 59, } A = \frac{6\,600\,000}{300 \times 86} = 256$$

Example 23. The same quantity of the same liquid as in Example 22 is to be used as it cools to heat boiler-feed water, by passing the liquids in a counter-current direction through concentric pipes. 10 000 lb of water per hr are to be heated from 50° to 160°. Find required heating surface; also the required surface should it be desired to raise the final temperature of the feed water to 160°. The heat required to be transmitted will be $10\,000 \times 100 = 1\,000\,000$ B t u, hence fall in temp of solution will be $1\,000\,000 \div (50\,000 \times 1.2) = 16.7°$, and final temp will be 153.3°

$$\text{By Eq 60, } t_m = \frac{(153.3 - 50) - (170 - 150)}{\text{Nap log}\left(\dfrac{153.3 - 50}{170 - 150}\right)} = 50.5$$

From Table 31, assume $U = 60$, whence from Eq 59, $A = 1\,000\,000 \div (60 \times 50.5) = 333$ sq ft. For second case, $Q = 1\,100\,000$; final temp of sol = 151.6; $t_m = 52.1$; $A = 464$; showing the large increase in area needed for increased final temp of the cold liquid as it approaches the initial temp of the hot.

Capacity of boilers and other heat-transfer apparatus is usually expressed in BOILER HORSE POWER (b h p). A b h p was originally assumed to be such that a boiler of a certain hp would supply enough steam to run a steam engine of the same hp. The term became too indefinite, since engines differ widely in consumption of steam for 1 hp, and the following definitions were adopted by the Am Soc of Mech Engs.

1 b h p = 34.5 lb steam made at standard atmos press, or temp of 212° F per hr from feed water at 212° F, or 33 305 B t u absorbed per hr.

Originally these terms were equivalent, but later investigations show that if the first definition is true the second should be 33 479 B t u. The first is generally used for ordinary feed-water temp and steam press, 34.5 lb from and at 212°, as it is ter- not differ greatly from 30 lb under common conditions, and this being an even is generally used as the h p unit for rating boilers, feed-water heaters, condensers. That is, a feed-water heater of 100 b h p capacity will heat $30 \times 100 = 3\,000$ per hr. Boilers require from 10 to 12 sq ft of heating surface per hp, depending on and are frequently rated by dividing the sq ft of heating surface by these numbers.

Efficiency of a boiler is the ratio of the heat absorbed by the water steam to that in the coal and may be separated into 2 parts:

$$\left.\begin{array}{ll} (a) \text{ Furnace effic} & = \text{heat liberated} \div \text{heat in coal} \\ (b) \text{ Surface effic} & = \text{heat absorbed} \div \text{heat liberated} \\ (c) \text{ Total boiler effic} & = a \times b = \text{heat absorbed} \div \text{heat in coal} \end{array}\right\} \quad (65)$$

ler effic defined above is sometimes designated as boiler and furnace effic. Among ses tending to reduce furnace effic are coal lost to ash pit, carbon burning to CO rd of CO_2, H, and hydrocarbons passing out of stack unburned; that tending to : surface effic is the sensible heat of the stack gases above the room temp. As gases can not be cooled below steam temp, the heat required to warm them from temp to steam temp is often called the necessary loss. For description of a com- heat balance, defining each loss and a manner of determination, see (18).

15. Entropy and Entropy Diagrams

finitions. Just as work may be expressed as the product of press and hange, when these quantities are expressed in proper units, so may heat pressed as the product of temp and the change in a quantity termed en- . One of the best definitions of entropy is that it is "heat per degree of rature." In engineering calculations it is the CHANGE IN ENTROPY dur- process, rather than the ABSOLUTE ENTROPY at any one time, which is tant; hence any arbitrary zero of entropy may be chosen.

steam work the zero generally taken is that of 1 lb of at 32° F, and in steam tables (Art 12) the values given ove that value as a base. For ordinary work on gases int in the process having the least entropy is selected zero. Entropy is usually designated by the Greek ϕ, and a diagram drawn to temperature-entropy coor- s is the $T\phi$ or heat diagram, precisely as one drawn to ordinates is the P-V or work diagram. The area rep- ing the amount of heat change during a process is the der the curve down to line of zero temp, this quantity expressed to the absolute scale. Thus, in Fig 23, the hange from A to B is represented by area $ABCD$.

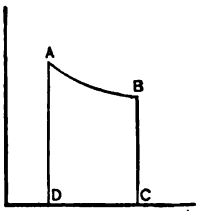

Fig 23

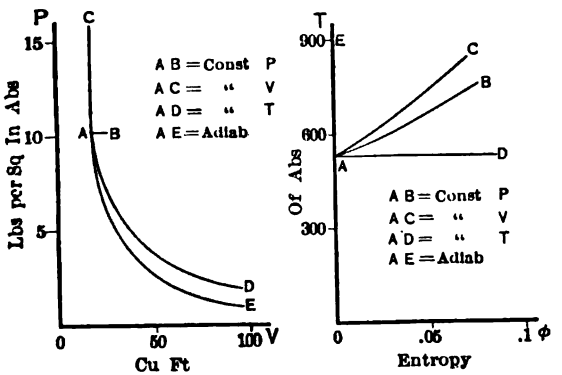
ange in entropy, being the change in heat divided by the temp at which urs, is simply expressed if the change takes place at constant temp. If mp is also changing, a differential form is required, for which a relation



g 24. Constant Press, Vol, Temp, and Adiabatic Lines, for Air to P-V and T-ϕ Coordinates

:en heat and temp is necessary. This is found in the quantity known as fic heat, and the change in entropy is found by integrating. The results iven in Eq 62 for constant specific heats, the expressions resulting from ng specific heats being too complex for general use.

$$\left.\begin{aligned}
&\phi_2 - \phi_1 = w\,Q \div T, \text{ for constant temp}\\
&\phi_2 - \phi_1 = w \text{ Nap log } (T_2 \div T_1), \text{ for water (sp ht = 1)}\\
&\phi_2 - \phi_1 = wC_v \text{ Nap log } (T_2 \div T_1), \text{ for gases at constant vol}\\
&\phi_2 - \phi_1 = wCp \text{ Nap log } (T_2 \div T_1) \quad " \quad " \quad " \quad " \quad \text{press}
\end{aligned}\right\} \quad (1)$$

For superheated vapors the values for gases may be used with fair accura especially for high degrees of superheat.

The four commonest processes, isothermal and adiabatic expansion, cons press-vol change, and constant vol-press change for gases, are shown in F to P-V and T-ϕ coordinates.

Temperature-entropy diagram. For vapors 2 entropy diagrams used, the temp-entropy and the B t u-entropy or Mollier diagram. Fig shows on a small scale the temp-entr diagram for steam.

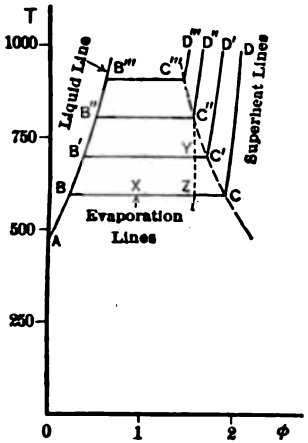


Fig 25. T-ϕ Diagram for Steam

The liquid line ABB''' represents the he of water from 32° F, the area below it deno the heat required, or the heat of the liq any point above 32° F. Lines BC, $B'C'$ represent steam-making at constant tem area under any horiz line denoting the la heat at that temp. The third group CD etc, represents superheating at constant Lines of constant vol, constant quality or stant heat may also be added (omitted fr diagram for clearness). Adiabatic expans compression is represented by a vertical l of the chief uses of the diagram is to deter the quality after an adiabatic change. length of any of the horizontals BC is eq the latent heat divided by the temp. Sho steam be wet all of the latent heat will be used; hence the line will be shorter and move to the left to some indefinite posit Then as BX is proportional to the quanti latent heat used, and BC to all the latent for the same press, $BX \div BC$ is the percent of steam present, or the dryness fractio $XC \div BC$ the percentage of moisture present. The quality after any adiabatic can be quickly determined by projecting from the original point up or down on the gram. For example, if adiabatic expansion occurs from point C (representing dry at some press), when the press drops to Y the quality will be $B'Y \div B'C'$, and w pressure Z is reached, the quality will be $BZ \div BC$. The diagram shows that ad expansion of dry steam causes wetness, expansion of superheated steam cause superheat, and expansion of very wet steam causes drying. Compression under t conditions causes the reverse action. For more complete description see (1).

Mollier diagram for steam, drawn to as large a scale as possible, is shown Fig 26. This, named from its originator, Prof Mollier, is of much w than the temp-entropy diagram. On it, horizontals are lines of tota verticals, lines of constant entropy; lines nearly horiz but sloping toward lower right-hand corner represent constant quality, and lines making an an of more than 90° with them are lines of constant press. By projecting to side from the intersection of a quality and press line the total heat may be directly, or the entropy by projecting downward. Adiabatic expans compression is represented by a vertical line, constant total heat by a hori

The greatest use of the diagram is in solving Rankine-cycle problems; Ex for effic and for velocity of steam jets. To find the work done in a Rank cycle it is merely necessary to read the total heat corresponding to any g press and quality, project from the original point downward to the line rep

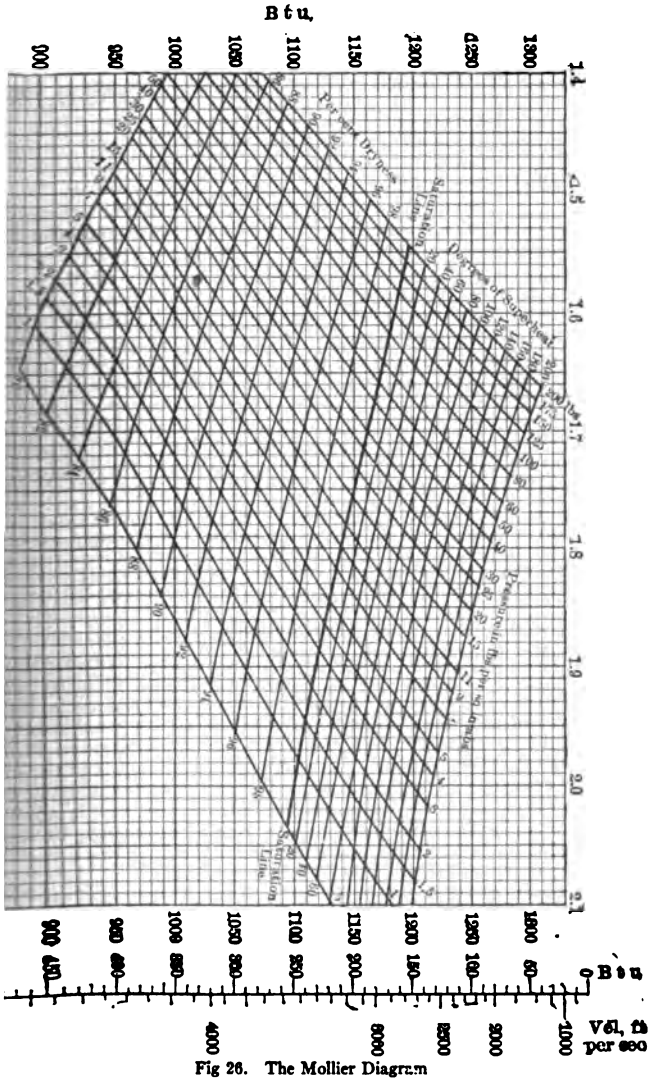

Fig 26. The Mollier Diagram

g final press, read the total heat at this point and subtract the two. The quality needed for determining m e p is found from the nearest quality ntersecting the final press line.

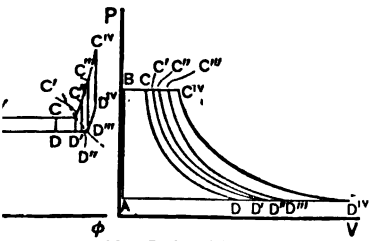
not cycle, which assumes complete adiabatic expansion and compression, rmerly universally accepted as standard, chiefly because it was the most it cycle between any 2 temperatures, and hence for steam pressure limits. ic depends only on the temp, or,

$$\text{Carnot-cycle effic} = (T_2 - T_1) \div T_2 \qquad (65)$$

T_2 and T_1 are the high and low abs temp, respectively.

ıkine cycle assumes complete adiabatic expansion, but no compression, now widely used as a standard of comparison, chiefly because it repre-an effic more nearly attainable, is equally applicable to superheated and steam, and serves as well for a basis for turbine work as for engine work, es not possessed by the Carnot. A common procedure is to speak of s as attaining a certain fraction of the Rankine cycle possibility.

ig 28 the constant-vol, press-rise line of the P-V diagram is represented on the liagram by a liquid heating line, which is substantially a constant-vol process. Heat is added from A to B and then from B to C, C', etc, as the case may be, adiabatic expansion follows to D, D', etc, and finally heat is removed from D, D', etc, to A. Considering one case only, that of initially dry steam, for example (as the rest are similar), the heat added is $H_{C'} - H_A$, that removed $H_{D'} - H_A$, and the work done is $(H_{C'} - H_A) - (H_{D'} - H_A)$ or $H_{C'} - H_{D'}$. Thus, the work of the Rankine cycle is merely the difference in the total heats at beginning and end of expansion. That at beginning is readily found



3. **The Rankine Cycle, with Different Initial Qualities**

e **steam tables** (Art 12), when the initial press and quality are known, or from llier **Diagram** (Fig 26). The final quality is not known, but can be computed or adily obtained directly from Fig 28. For method of computation, see Example 26. l be $(H_{C'} - H_{D'}) \div (H_{C'} - H_A)$, H_A being the heat in the liquid at beginning of the r at the temp corresponding to the back press, and may be found from the steam The m e p is the work done divided by the vol change, and since originally there is uid present, the vol of which may be neglected as it is very small compared to the

final vol, the vol change may be taken as equal to the final vol. tabular value (from steam table) times the quality, if wet, and a divided by the saturation temp, both absolute, if superheated. equally to turbines, and all of the above except the expression for to both piston engines and turbines. But, there is one more quanti bines only, viz, the velocity of the jet. Considering 1 lb of steam and ity, the final velocity will be $\sqrt{2\,gW}$ or $8.02\sqrt{H_{2'} - H_{2}}$. These ex in Table 32.

Table 32. Rankine Cycle

Work	$H_1 - H_2$
Efficiency	$(H_1 - H_2$
M e p (lb per sq in)	$778\,(H_1 -$
Heat consumption per hr per h p	$2\,545\,(H_1 -$
Steam consumption per hr per h p	$2\,545$
Jet velocity	$\sqrt{(H_1 - H_2}$

H_1 is the heat in the liquid at the low press; H_2, the heat in the st sion; H_3 the heat in the steam after expansion.

The thermal effects of change of initial press, back press, superheating and reheating, in a steam engine are best seen from examination of Rankine cycle. In Fig 29 (a), $ABCD$ represents a cycle between t

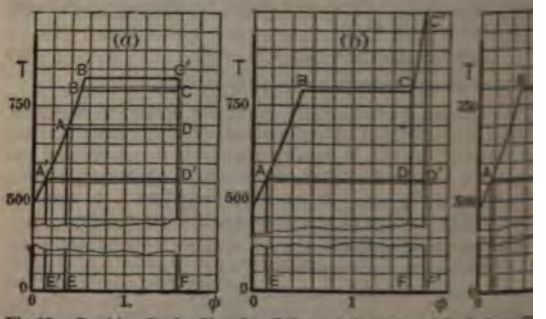


Fig 29. Rankine Cycles Showing Effect of Initial and Back-Press C Reheat, and Jacketing

lb and 20 lb, the area being proportional to the work of 1 lb of initially d shows the case for an initial press of 160 lb, all other conditions being in work being $BB'C'C$. $A'BAD'$ is the case of the original initial pr press lowered to 1 lb, the gain in work being $A'ADD'$. Thus, the gai is considerably greater than for the former, although the change in ciencies in the 3 cases are: $ABCD \div EABCF$, $AB'C'D \div EA'B'C$ $E'A'BCF$. Increase of initial or decrease of exhaust pressure both t efficiency. Complete expansion is assumed in all cases of the Rankine possible to realize in real engines with high ratios of expansion, that high initial or very low back press, so that the gains in cyclic perfe fully attained in practice or may possibly be losses.

In Fig 29 (b), $ABCD$ represents the work of a cycle for saturated st press limits, and $ABCC'D'$ for steam with 300° of superheat and th the area $DCC'D'$ denoting the gain in work. Efficiencies for the s $EABCF$ and $ABCC'D' \div EABCC'F'$. It is obvious that superhe thermally with but little increase in efficiency. In pra ages and heat transmission losses generally produce a be expected from the cyclic effect.

cle $ABCD$ is for saturated steam with adiabatic expansion, and $ABCD''$ ith jackets imparting heat enough to the steam to cause it to remain xpansion. Other cases, in which insufficient or more than sufficient g expansion to produce continued saturation, are possible, but ideally hermal efficiency and in practice either a loss or such a small gain as the use of jackets inadvisable. Cycle $ABCxyzD'$ represents the case rtial expansion, a process, if used at all, occurring between the cylinders sion engine, or between an engine and a low-press turbine. Point X, is allowed to proceed, is arbitrary, as is also the reheating temp. A to make the receiver pressure X such that equal work is done in eheating can not well be carried above the original temp. As with e to reheating is either negative or too small to warrant its use on s for the 3 cycles in Fig 29(c) are $ABCD \div EABCDF$ for the original, F'' for jackets, and $ABCXYZD' \div EABCXYZF'$ for reheating.

nd the cyclic effic, water, and steam consumption of an engine oper- of 140 lb abs, with 100° superheat and back press of 10 lb abs. Also for same press drop, and the m e p.

ables (Art 12) the heat at beginning of expansion is 1 248 B t u, and e liquid at 10 lb abs (= 193° F) is 161 B t u. The quality after ex- follows. The entropy originally (Table 25) is 1.6395, and since ex- the final entropy must have same value. The total entropy of steam ts if wet, or 3 if superheated, precisely as is the total heat. If for y is less than the dry saturated value for that press, the steam is wet opy must be part of that of evaporation; the percentage of moisture ssing entropy divided by the entropy of evaporation for the given dry steam at 10 lb is 1.7874, hence the amount missing is 1.7874 − As the entropy of evaporation for this press is 1.5042, the percentage r dryness is approx 90; hence, the total heat is 1 045 B t u. The final ead directly from a temp-entropy or a Mollier diagram (Art 15).

e effic will be (1 418 − 1 045) ÷ (1 240 − 161) = 18.7%. Steam con- 2 545 ÷ (1 248 − 1 045) = 12.5 lb, and jet velocity

$$= \sqrt{(1\,248 - 1\,045) \times 778 \times 64.4} = 3\,190.$$

g 90%, the final vol will be 90% of the tabular, or 0.9 × 38.4 = 34.6 p = 778 (1 248 − 1 045) ÷ 144 × 34.6 = 37 lb.

uld be obtained with practically no calculation by the Mollier diagram, s worked by that method in Art 15.

STEAM ENGINES

1. Classifications and Characteristics

sifications. I. SIMPLE ENGINES: (*a*) high-speed, single valve; (*b*) high-speed, alve; (*c*) medium and low-speed, multivalve. II. COMPOUND ENGINES, with or t receiver: (*a*) tandem; (*b*) cross-compound; (*c*) duplex. Each may be high, n, or low speed, and they are generally multivalve. SPEED CLASSIFICATION is based itive speed, not piston speed; 175 to 500 r p m being classed as high speed, 110 to) m, medium speed, and less than 110 r p m, low speed. PISTON SPEED is the r of linear ft piston travel per min. In different types of engine, it ranges from 750 ft per min, short-stroke engines having the lower speed, long-stroke, the higher. am engines are double acting, excepting a few special types, and all are built in the horiz or vert form (1, 3, 4, 5).

gh-speed, single-valve, simple engines are made in sizes up to 500 hp. are low in first cost, but have rather high steam consumption. Simple en- are rated at some definite steam press and approx 0.25 cutoff (about the economical point for non-condensing). For simple, condensing engines, the conomy is at ⅛ to 0.2 cutoff, at which they carry a 25% overload without y increasing the WATER RATE (lb dry steam per ihp-hr). Water rate in- s rapidly as the load falls below 50% of rating.

t engines of this type have automatic cutoff governor; sometimes a throttle gov- A throttle governor reduces initial cost, but cannot give close speed regulation, wasteful of steam when the engine runs at loads much below its max power.

gh-speed, multivalve, simple engines, because of the greater number of have higher first cost than single-valve engines and require more care, but regulate more closely and their steam consumption is lower. They are in sizes up to 1 000 hp.

edium and low-speed, multivalve, simple engines are made in sizes up to hp. Corliss or trip valve-gear is practically confined to low-speed engines, he 4-valve gear may be used for any speed. Unit steam consumption of ium and low-speed simple engines is lower than that of high-speed, single- , simple engines of same power and operating under same conditions, but is little difference in this respect between them and the high-speed multi- engine.

mpound engine, theoretically, has no better efficiency than a simple engine. ractical advantages are: lower leakage and condensation losses, higher ratio pansion, and more uniform crank effort. Initial and repair costs are higher, he space occupied per hp is greater. They are made in sizes up to 6 000 hp etimes larger). Diams of high and low-press cyls are proportioned to lize the work approx between the two, when the engine is run at its rated

To do this the ratio of piston areas depends upon the ratio of expansion een initial steam press and back press, ranging from about 1 : 3 to 1 : 6.

large compound engines the low-press cyl is sometimes divided into 2 cyls, to avoid ifficulty of making very large cyls and the still greater difficulty of properly balancing reciprocating masses. In order that the low-press cyl may not be unduly large respect to the rest of the engine, and hence increase cost of manufacture, steam is r expanded below 6 lb per sq in, when the engine is operating at its rated load. pting some locomotive engines and a few smaller types of stationary engines, com- d engines are designed to operate with a receiver between high and low-press cyl.

iple and quadruple-expansion engines are seldom built except for marine use. e some of the best thermal effics on record have been made by them (generally in ng large pumps), their very high first cost has caused them to be supplanted by n turbines.

2. Sizes, Powers, and Speeds

Water-rate, in its generally accepted sense, means lb of st per ihp-hr. Table 1 gives the averages to be expected fro

Table 1. Average Water Rates of Steam Engi

Type of engine	Water r lb. per h
High-speed, simple, single-valve, non-condensing	3

Low-speed, " non-condensing	2
" " " condensing	1

operated at rated load under normal steam press with saturat superheated steam reduces the water rate by 5 to 20% for each heat. Reduction in coal consumption will be less, as some of th must be used for superheating the steam, unless waste heat is u liarities in load conditions also cause water rates to vary.

Cost of steam engines varies widely with size, make, speed, gearing. The following aver costs (*Engineering*, Nov 15, 190 for comparison:

	Cost (dollars)		
Simple high-speed engines.	"	"	30 +
Compound high-speed engines.	"	"	1 20 +
Simple low-speed engines.	"	"	1 20 +
Compound low-speed engines.	"	"	2 00 +
Setting, high-speed engines.	"	"	60 +
Setting, low-speed engines.	"	"	300 +

Following tables are abridged from builders' catalogues. Each en operated satisfactorily at steam pressures and speeds other than those sponding variation in hp. Builders' catalogues should be consulted for types other than those listed.

Note. — Horsepowers are based on cutoff at ⅓ stroke, and, when condensing, on vac of 25 in. Engines should not be operated at pressures exceeding those for which pow are given. The 8 & 14 × 8 engine as listed is built for press up to 180 lb; a lighter de is built for a limit of 125 lb.

3. Valves and Valve Gearing

Single slide valves, driven directly by eccentric, are used in low-power, high-sp engines, and in the cheaper forms of medium-power, high-speed engines. The s plicity of this valve gear and its non-liability to derangement, make it especially u ful for small mine hoists. DIAGRAM FACTOR (Sec 39, Art 4) of simple slide-valve engi ranges from 50% in smallest sizes to 85% in the largest. Distortion of the diagram particularly noticeable at very short cutoffs. Corliss valves are limited to a speed of greater than 125 rev per min. Their diagram factor ranges from 85 to 90%. They advantageous for intermittent-running engines, such as hoists, in that they may be thro by hand, for admitting steam to the cyl even if the piston has passed the normal point cutoff. For the better class of high-speed engines of medium and high powers, valv are used (as in the Corliss gear), but are fixed rigidly to their gearing and not trip like the Corliss. Diagram factors for ordinary 4-valve engines (those having separ admission and exhaust valves at each end of the cylinder) average slightly lower th for the Corliss. Double slide valves, driven by separate eccentrics, are used on some typ of engines, with results similar to those of the 4-valve gear. SETTING ENGINE VAL For details see Bib (1, 3, 4), also Kent's Mech Engs Pocketbook, Ed 1913, pp 103 1047.

In Europe, poppet valves have long been used on medium and high-power engin particularly with superheated steam. They are actuated by a cam shaft, geared to th main shaft. Their diagram factors range as high if not higher than those of Corliss valv A few poppet-valve engines are now being made in this country, and it seems probab that their use will be extended.

4. Special Types

Rotary engines form the largest class of steam engines other than those already de scribed. To 1915 none has been produced which can compare in steam economy wi reciprocating engines of same power and operating under same steam conditions. Mo of them are wasteful of steam even when new and become rapidly worse with wear. Th only valid claims made for them are high speed and lack of vibration. These feature are also true of the steam turbine (Art 5–7), which is now made in small sizes with steam consumption approaching that of the best reciprocating engines, and in large sizes ha displaced the reciprocating engine for all except special purposes.

"Unaflow," or straight-flow, engine derives its name from the peculiarity of th steam cycle. The inlet valve, generally of the poppet type, admits steam in the usual manner at beginning of stroke, but the exhaust port, which has no valve, is uncovered by the piston at end of stroke, and all of the steam remaining in the cyl when the exhaust port is covered by the returning piston is compressed into the clearance. Hence the steam flows through the cyl in one direction. These engines cost more than simple

es of same power, but their steam consumption is as good as that of high-grade ound engines. Also, their steam consumption per hp-hr varies but slightly over a range of load.

STEAM TURBINES

5. Principles and Operation (9, 10, 11, 12)

finition. A steam turbine utilizes the expansive energy of steam in its kinetic as distinguished from reciprocating or rotary engines, in which the steam acts by essure directly upon a piston.

al steam turbine receives steam at line press, utilizes all the expansive energy elerating flow of the steam, and discharges it at the exhaust press at zero velocity, ut loss by friction, impact, or radiation. This result is attainable only by trans- g all the momentum of the steam to moving parts. The chief difficulty in design- machine to approach the ideal is the economical utilization of the high velocities o expanding steam; thus, expansion of steam between the ordinary limits of line xhaust press will give a steam velocity of 3 000 to 4 000 ft per sec. The number igns on the market indicate the numerous attempts made to overcome this difficulty.

thod of operation is shown by Fig 1. *BMC* is the cross-section of a turbine vane. ner surface of which turns through 180°. *AB* represents in length the veloc of a jet. If the vane is at rest and there is no on loss, the jet will be turned in the opposite tion and leave the vane with veloc *CD*, equal 3. In this case no work is done, since there is ange of momentum, as would also be the case vane were moving at same veloc as the jet. if the vane moves at veloc *III*, the relative of the steam to the vane will be $AE = AB$ *I*. Relative veloc of the steam leaving the is $CF = AE$. But, since the vane has an absolute veloc *IH*, the absolute residual of the steam equals *FG* and is in the direction of the motion of the vane. Hence, vane be moving at half the veloc of the jet, the steam will be brought to rest on leav- he vane. But, as there must be a series of vanes in a practical turbine, it is impos- sible to turn the steam through 180° in the same plane without mutual interference.

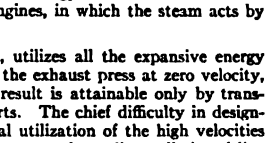

Fig 1. Steam Turbine, Velocity Relations

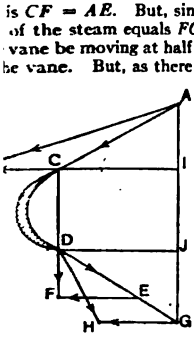

2. Operation of Steam Turbine

Fig 2 shows the principle of a practical turbine. Line *AB* represents veloc and direction of the steam jet, *CB* the veloc and direction of the vane. Then *AC* is the relative veloc and direction of jet to vane. If there be no friction loss, *DG* represents the relative exit veloc of the jet, and this, solved with *GH* (= *CB*) the veloc of the vane, shows the residual absolute veloc of the jet to be *DH*. But, due to fric-

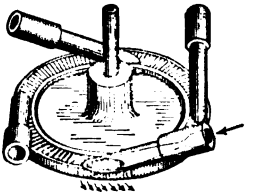

Fig 3. DeLaval Turbine

loss, the exit relative veloc will be represented by some length of line, as *DE*, which n with the veloc of the vane ($CB = GH$), shows the residual absolute veloc of the be *DE*.

avoid impact losses the jet should enter the vane tangent to its face; in this case ntrance angle is equal to the angle *ACI*. Thus, for best conditions, the angle of , veloc of vane, and veloc of jet are interdependent. In Fig 2 the exit angle of vane ual to entrance angle; a common construction, though by no means necessary. 3 shows a diagram of the DeLaval turbine, with casing removed; it is the simplest of impulse turbine.

Impulse and reaction turbines. In the impulse type all the veloc, and hence kinetic energy, is generated outside of the moving parts; in the reaction type, with the moving parts. No commercial turbines operate solely on the reaction principle but those using a combination of both principles are commonly known as reaction turbines for example, the true Parsons design.

Commercial types. The vane veloc must be very high if the entire energy of expanding steam is to be utilized in a single wheel. The great variety of commercial designs results from efforts to produce an economical turbine with a shaft speed low enough for the direct drive of ordinary machinery. The chief modes of meeting this problem are: (*a*) A single impulse wheel of large enough diam to bring the shaft speed and linear speed of vanes within the required limits (not used in any American turbines). (*b*) A single wheel of small diam, connected to the main shaft by gearing. Fig 4 *A* shows the principle of the simple impulse turbine. (*c*) A single-pressure stage with 2 or more wheels in it, each of which removes part of the energy (Fig 4 *B*). (*d*) A number of pressure stages, in which, by dividing the press drop, the development of energy is divided and hence the velocity in any stage is reduced. Each of these stages contains either a simple impulse wheel or is velocity staged. (*e*) Pressure staging and the utilization of the reaction principle; commonly known as the Parsons type. Fig 4 *C* shows its operation. Guide vanes, taking the place of nozzles, extend around the entire circumference. The pressure, as shown, is caused to drop in both guide and wheel vanes. The object is to generate only such velocity as can be utilized at the point where it is generated. The veloc in the guide vanes is sufficient to allow the steam to enter the moving vanes without shock. This gives a certain impulse effect. Expansion in the wheel vanes adds to the veloc, and the steam gives a reaction effect on leaving them. Only 3 stages are shown in the diagram, but commercial machines are made with 50 to 70 stages.

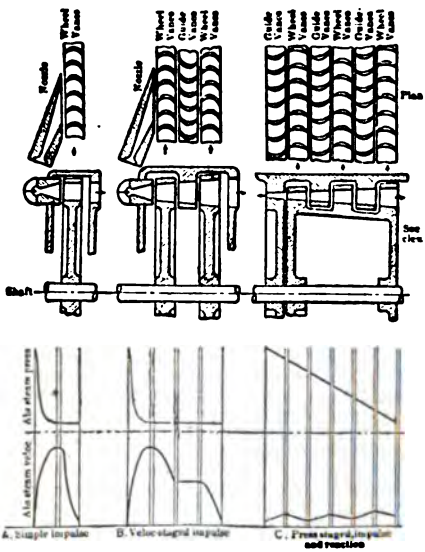

Fig 4. Diagram of Action of Steam in Different Types of Turbine.

The above types are divided among the various makes as follows: *DeLaval*, small size, 1 wheel with gearing; larger sizes, veloc or press-staged, 1 wheel in each stage. *Terry and Sturtevant*, velocity staged, with 1 press-stage. *Rateau and Zoelly*, press-staged, 1 wheel in each stage. *Curtis*, press-staged, and veloc staged with each stage; also pressure staged with the first stage, veloc staged, the remaining stages having a single wheel each. *Westinghouse*, small size, press-staged, with veloc staging in each. *Westinghouse-Parsons*, press-staged, utilizing reaction principle; also first stage impulse veloc-staged, and remainder press-staged reaction. *Allis-Chalmers-Parsons*, press-staged, utilizing the reaction principle.

6. Losses and Effect of Steam Pressure, Superheat, and Vacuum

Principal losses are: leakage losses past vanes, nozzle friction, impact on vanes, friction on vanes, and the friction of the wheels revolving in a steam atmos-

, the last being generally known as windage loss. Condensation, a large r in reciprocating engines, is unimportant in turbines, since there is practi- no variation of temp in any of the steam passages.

gh steam pressure is desirable and low back-press is particularly important. iprocating engine can not utilize expansion of steam down to a low back- as it would require too bulky a low-press cyl, but a turbine may be designed steam down to the highest vacuum. For relative work of steam at high ow press, see Sec 39, Art 4, 10. The use of superheated steam in turbines ises the friction losses, but the extent to which the superheat temp may be d depends upon cost of superheating, which varies according to conditions.

thods of governing. All low-power turbines, to approx 300 hp, maintain their under varying load conditions by throttle governing. From Art 5 it is seen that ethod is uneconomical, since for a given vane veloc the steam veloc for best condi- s fixed. In a few small turbines, some of the nozzles may be shut off by hand, when ing at low loads, thus allowing the remaining nozzles to operate at more nearly the steam press. The larger sizes of impulse turbines are governed by automatically g out and cutting in some of the nozzles. In the pure Parsons type, as steam is ad- over the entire periphery, the whole steam supply is interrupted periodically, the s being controlled by governor.

w-pressure turbines. A number of turbines have been installed to operate am at approx atmos press, with a high condenser vacuum. Some take the st from non-condensing, reciprocating engines, deriving more power from it the latter engines could, because turbines work with very low back-press.

he 59th St power station of the Interborough Rapid Transit Co, N Y, low-press es are attached to 7 500-kw reciprocating engines. Nearly all such installations een made to increase the capacity of an old plant, and there is rarely any economy an arrangement over a turbine installation.

re are several low-press turbine installations in which the turbine is supplied with from exhaust of engines, or other steam apparatus, which operate intermittently. cal case is at the Wisconsin Steel Co's works, South Chicago. The steam for the comes from the exhaust of rolling mill engines, which, when operating, deliver team than is needed by the turbine. Between engine and turbine there is a "re- tive accumulator," essentially a large horiz cyl, partly filled with water. When the of exhaust steam exceeds the turbine's need, the excess condenses and raises ap of the water. When the exhaust falls low or ceases, the turbine demand reduces ess in the accumulator, and steam is evaporated from the hot water. An auto- valve admits line steam to the turbine when the accumulator press falls below a ermined point. The accumulator is guaranteed to supply the turbine at its full 500 kw for a 5-min total interruption of steam supply. This device might ad- eously be used in connection with mine hoists.

7. Cost, Steam Consumption, and Weight

t of turbines varies with type and conditions of service. This is especially f the smaller sizes. The figures in Table 6 are average or approx. They e cost of generator, and of freight and erection, within 600 miles from s' shops, but not of auxiliary apparatus.

am consumption depends upon type, size, steam press, initial superheat, acuum. For any given case a much closer result than in Table 6 is ob- le by working out the Rankine cycle hypothetical water rate for the actual ions and modifying it by the effic *vs* Rankine cycle, as in Sec 39, Art 16.

ght of turbines is less than for equivalent reciprocating engines. This fact, coupled lmost total absence of vibration, permits large saving in cost of foundation, and the turbine to be placed on structures which could not support a reciprocating The space occupied is much less than for reciprocating engines.

Most of the data in the following table are from curves by H. G. Stott, R. J. S. P and W. S. Gorsuch (Amer Inst Elec Engs, June, 1914).

Types of service. Turbines operate at best effic when driving electric gener centrifugal pumps or fans, and other constant-speed machines. BOILER PLANT

8. Types of Boilers (1, 2, 3, 4, 5, 6)

General design must be such that natural circulation will draw the fe [illegible] through the cooler portion of the boiler, where it is gradually heated, a steam generated has free ac- cess to the space above water level.

No part of the boiler in con- tact with the hottest gases should form a pocket, as the steam generated in it would tend to force the water away and per- mit the metal to become over- heated, with danger of rupture. Boilers must withstand [illegible] [illegible] without dis- [illegible]

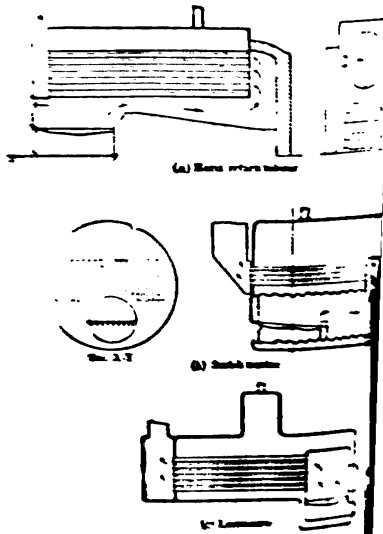

Fig 5. Fire-tube Boiler

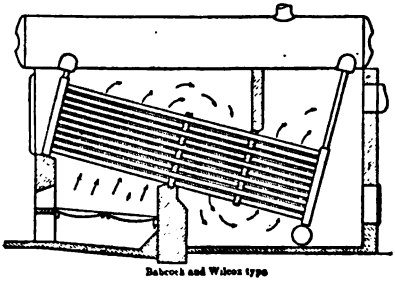
[illegible] large longitudinal flues, and [illegible] [illegible] contents. All these are now classed

dern **boilers** are of 2 general classes: fire-tube, in which the gases pass through expanded into headers forming part of the shell; water-tube, in which the water is tubes, the gases passing around them. Of the numerous designs only a few charactic types are herein described.

e-tube boilers are either internally or externally fired. Fig 5 *a* shows TERNALLY-FIRED, horiz, return-tubular boiler. The heads are connected to 4-in tubes, expanded into them. First cost is low and they are widely for moderate steam press and capacities of less than 200 boiler horsepower . The Scotch marine and locomotive types, Fig 5, *b* and *c*, are examples of NALLY-FIRED fire-tube boiler.

motive type is good for small temporary plants; having no setting, it is portable. nerally made in sizes of less than 100 bhp and for steam press of 70 to 125 lb gage. marine boiler has a corrugated firebox, extending through the shell, the gases ng through the tubes. The firebox corrugations relieve expansion strains due to s of temp. These boilers are very satisfactory in moderate size plants. Coms and absence of radiation losses characterize internally-fired boilers.

ter-tube boilers. Fig 6 shows 3 representative types; Babcock and Wilcox ably the best known. It meets practically all essentials of good design, like most other tube boilers, is transported, since t is of great weight. ade in sizes up to hp. Many other resemble the B & neral form. Some riz instead of veraffling. Stirling is a well-known rather cheaper e B & W, and has nade in units as as 2 350 bhp. y boiler is of same s the Stirling. It mparatively small s, each consisting umber of tubes ing 2 drums. As ections as necesay be connected r in a setting to single boiler, up s of over 2 500 Wickes boiler is r well-known ADVANTAGES of be over fire-tube they are faster s, may be obtained in much larger units, are easily transported, and a is less likely to cause disastrous explosion.



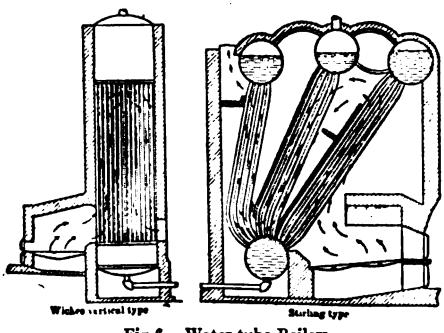


Fig 6. Water-tube Boilers

9. Boiler Attachments

offs. A blow-off pipe and cock must be connected to the lowest part of the This is for drawing off the water, when necessary, chiefly for blowing out sedi-

ment and scale. The blow-off is sometimes attached to a MUD DRUM connected to t bottom of the boiler. Surface blow-offs may be connected with the boiler at the wa surface, for blowing off scum caused by impure feed water or presence of oil.

Water column is a metal chamber with a GAGE GLASS on one side (for observing t height of water in the boiler) and 3 TRY COCKS on the other, for finding the water leve the gage glass is broken or stopped. Some water columns automatically blow a whis if the water is too high or too low.

Safety valves are essential. Legal requirements as to their design and method connection vary in different states and should be ascertained.

Fusible plugs, required by many state or municipal boiler laws, consist of a h plug with a fusible metal core, screwed into the boiler below normal water line and in path of the hot gases. While covered with water the temp of the plug is below t melting point of the core; if the water level falls below the plug the core fuses, allow steam to escape and press to fall. The plug is placed above the expanded joints of t tubes, which would be weakened by high temp and might rupture.

10. Ratings, Efficiency, and Costs (see also Sec 39)

Boiler horsepower (bhp) is defined as the transfer in 1 hr from the gases to t water of a quantity of heat sufficient to evaporate 34.5 lb water at temp of 212° to steam at sa temp. This is equ alent to 33 479 B per hr. *Note.*—Th is no relation wh ever between 1 h and an engine which is 33 000 ft of work per min bhp, under norm conditions of fe temp, and stea press, is approx equ alent to 30 lb of wa evaporated per a figure comm used for rough calculations, and accepted as a "commercial" bhp. Rat of boilers as to the hp they will develop is arbitrary; Table 7 shows th commonly used, including data as to relative dimensions of grates and rates combustion. Rate of combustion varies considerably with kind of coal, dra and mode of firing.

Table 7. Approx Proportion of Heating and Grate Surface per HP

Type of boiler	Sq ft of heating surf per hp	Coal per sq ft of heating surf per hr	Relative rapidity of steaming	Heating surf per sq ft of grate	Lb coal per sq ft of grate per hr	Lb water per lb coal
Water-tube...	10 to 12	0.3	1.00	35 to 50	12 to 20	9 to 12
Cyl tubular...	14 to 16	0.25	0.60	25 to 35	10 to 15	8 to 11
Vertical tube.	15 to 20	0.25	0 60	25 to 30	10 to 15	8 to 10

Plain cyl.....	6 to 10	0.5	0.20	15 to 20	15 to 25	7 to 9

Efficiency. For losses in boilers and furnaces, see Sec 39. Effic of th boiler is not 100%, since the temp of the furnace gases can not be r below the steam temp. A large number of tests on different types of bo grate, with different ratings and modes of firing, show a combined b furnace effic of 60 to 80%; aver about 70%. In ordinary operation approaching the aver may be maintained in large plants, with strict supervision, but in small plants the aver effic is probably not much over 55

Costs. Following formulas are approx (*Engineering*, Nov 15, 1902).
Horizontal water-tube. Cost (dollars) = 500 + (9.2 × rated hp).
Vertical water-tube. Cost (dollars) = 500 + (8.5 × rated hp).
Horiz tubular. Cost (dollars) = 100 + (6.5 × rated hp).
Small vert fire-tube. Cost (dollars) = 100 + (5 × rated hp).
Cost of the water-tube boilers is based on 125 lb steam press and re

ɛ surface per bhp; that for horiz return-tubular boilers on 12 sq ft heating
. Scotch marine boilers may be estimated on same basis as the water-
aking 8 sq ft per bhp.
of plain settings are roughly:
iz water-tube. Cost (dollars) = 400 + (0.8 × rated hp).
iz return-tubular. Cost (dollars) = 300 + (0.7 × rated hp).

11. Feed-water Purification (6)

rious substances occur in practically all water. They are detrimental either oilers or to their proper operation. Troubles from impure feed water are: forma- scale, corrosion, and priming or foaming. Solid matter may be precipitated as it, or may form scale on the heating surface. SEDIMENT causes little trouble; ularly drawn off at the blow-off (Art 9). SCALE seriously retards heat transfer, llowed to accumulate the heat may weaken the metal sufficiently to cause rupture. ION causes general weakening of the boiler, finally resulting in a breakdown at oint. PRIMING causes steam to carry with it more or less water, which, if it enters ine cyl in sufficient quantity, may blow-out the cyl head. Substances causing oubles may be natural constituents of the water, or be due to waste from a plant ory at a higher point on the stream from which the water is drawn. Where the sed steam from surface condensers is pumped back to the boilers the oil should be ely separated. Condensed steam from turbines does not give trouble, as oil is ily in the bearings.

tment. Scale-forming substances may be precipitated by heating, or by adding hemicals to the water supply and eliminated by filtration; or chemicals may be to the feed water to cause the solid matter to form as a sediment instead of in- g the heating surface. Anti-scale chemicals are known as BOILER COMPOUNDS. ces causing corrosion or priming are treated in a similar manner. Electrolytic sometimes causing pitting and corrosion, may be neutralized by hanging zinc plates he boiler.

Table 8. Feed-water Purification

ouble	Cause	Remedy
	Sediment, mud	Filtration
	Readily soluble salts	Blowing off. Heating feed water and precipitating caustic soda, lime, and magnesia
	Bicarb of magnesia.	
ation	Lime, iron	
	Organic matter	See below
	Sulphate of lime	Sodium carbonate Barium chloride
	Organic matter	Precipitate with alum or ferric chloride and filter
	Grease, oil	Add slaked lime or sodium carb and filter
on	Chloride or sulphate of magnesium	Sodium carbonate
	Sugars, acid	
	Dissolved CO_2 and O	Slaked lime, caustic soda; heating
	Electrolytic action	Zinc plates
	Sewage	Precipitate with alum or ferric chloride, and filter
s	Alkalies	Heat feed water and precipitate
	Sodium carbonate in large quantities	Barium chloride

ire feed water should be analyzed, to determine what it contains and the remedy, o the wt of solids in a given wt of water and hence the proper wt of chemicals to be for neutralizing. Boiler compounds, if used in excessive quantity, may them- ause boiler troubles. Avoid all secret preparations. They are either worthless ain ordinary chemicals for which a higher price is charged under the name of a

special preparation. In the latter case, it is only a matter of chance that the chem are suited to the water to be treated. A number of concerns make a business of tre impure water for boiler feed and industrial purposes. In case of bad feed water often satisfactory to put the problem in the hands of one of these companies. importance of the proper treatment of impure water is shown by the extensive pur tion systems installed by many large plants and factories.

12. Furnaces for Solid, Liquid, and Gas Fuels

(For the theory of furnace operation, see Sec 39, Art 13; for details of large subject, see Bib.) The best efficiency is the result of supplying just s cient oxygen to combine with all of the combustible. With solid fuels this impossible in practice, the greatest loss being frequently due to excess air ra than imperfect combustion.

Bituminous coal. The combustible is partly volatile matter and partly fixed ca the relative proportions varying widely (Sec 35). The volatile matter is driv rapidly by heat as hydrocarbon vapors. To effect combustion these vapors m intimately mixed with enough air while at a high temp. Contact with a relatively surface, as the boiler tubes, causes formation of soot and prevents combustion. M forms of furnace have been designed to overcome the difficulty. Some provide a s ate combustion chamber, where complete combustion is supposed to take place be the gas passes to contact with the boiler. Others, by natural draft or steam jets, duce air at the bridgewall or the furnace sides, and brick piers are sometimes arrange baffles thoroughly to mix the air and gases. Some of these designs are effective, resulting high temp often produces rapid deterioration of the brickwork. This has especially marked when certain substances in the ash form a flux for the fire prevented by analyzing the ash and using a firebrick with which it will not flux.

While special furnaces may assist in effecting good combustion, the best results obtained by intelligent and experienced firemen. Some concerns spend a large am on apparatus for improving efficiency, while refusing to pay wages that will attract firemen, or to hire a sufficient number. The fire should be kept even and without h Aver depth of bed for bituminous coal is 8 to 10 in, but this depends on the avail draft. The fire should not be allowed to become dirty, a dark ash pit being an evid that cleaning is necessary. An important rule is that the coal shall be spread ever thin layers. In adding a heavy bed of fresh coal much of the volatile is driven off burning, since the temp above such a bed is too low. Instead of spreading the fresh on the fire, it may be piled on a dead plate in front, where the volatile is distilled remaining coke being then pushed over the fire. This is satisfactory only when fire is being carried.

Anthracite coal (Sec 34), containing comparatively little volatile matter, is hand differently from bituminous. Steam sizes form a dense bed, presenting con resistance to the passage of air. Hence the can not be thicker than 3 or 4 in. and the tion of holes or thin spots must be a This is more important than with bitumi coal and efficient firing is more difficult.

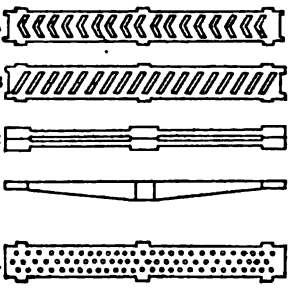

Fig 7. Boiler Grate Bars

Grates for hand-fired furnaces are stati or rocking. STATIONARY GRATES requ the ash be pulled out through the fire make it difficult to keep air spaces thr ash and clinker. ROCKING GRATES are numerous forms, worked or dumped by at the front of the boiler. Grates are di into 2 or more sections, so that the co be piled on one part while cleaning an Fig 7 shows ordinary forms of grate bars the herringbone, *B* is a Tupper, and common straight bar, all in plan. *D* sec elevation. Grate bars are generally about 3 ft long, and when used in a rocking this makes 1 dimension of a section, the other dimension depending on size of ma

mber of grate sections. Size of air space must be suited to the kind of coal; if too nuch fuel may be lost in the ash. *E* is a PINHOLE GRATE, used for burning saw- ıd other small sizes of fuel. Hand-fired furnaces should not be longer than 6 ft ıminous coal; beyond that, it is difficult to slice the fire. Furnaces for anthracite : 10 or 12 ft long, as no slicing is required.

chanical stokers. Advantages over hand-firing: (*a*) coal is fed continu- instead of intermittently, permitting a constant air feed of proper propor- whereas with hand-firing the air supply should be large directly after firing nstantly decreased until time for next firing; (*b*) the fire is kept even, with ıuent reduction in amount of excess air passing through thin spots and (*c*) the gases maintain a high, even temp, while with hand-firing, the g of a door often reduces the temp as much as 200 or 300°; (*d*) labor of is greatly reduced. But, it can not be too strongly emphasized that nical stokers will not give good results unless they are constantly super- ɔy an experienced man. Hence, while they are practically essential for a ılant, they may not show any net saving in a small plant (6).

sification of mechanical stokers: step grates, chain grates, and underfeed. STEP are arranged in a series of steps. Each grate (in some cases, alternate grates) ed from a horiz to a forward inclined position. A rocker arm connects all the and is actuated from front of furnace. The rocking action keeps the fire broken the coal continually moving forward. Coal is fed to the top of the grate from a . Rate of combustion is determined by rapidity of the rocking action, thickness bed, and intensity of draft. The relation between these 3 factors must be so main- that all the fuel will just be consumed when the coal reaches the end of the grate, ı plate or dumping grate receives the ash. With some step grates the air is drawn n the bars; others use hollow bars, into the ends of which air is forced and admitted fire through narrow slits in the sides of the bars. Some grates incline from front t of furnace; others consist of 2 sections, each feeding from the side toward the . CHAIN GRATES are a continuous chain formed of grate bars, mounted on 2 Grate moves from front to back of the furnace, and is either horiz or slightly l. Coal is fed from a hopper in front. Depth of coal and speed of grate are regu- t will. General conditions of operation are practically the same as for the step When bituminous coking coal is used, special devices are installed to keep the ɔperly broken up. UNDERFEED STOKERS consist of a horiz trough or retort, into he coal is forced by a ram or screw. Air enters through tuyeres along the top edges retort. On each side are dead plates or grates, the bed of the fire lying above. ɔen coal in the retort is reduced to coke, the volatile matter passing up through the l in close contact with the air supply. As fresh coal is forced into the end of the the coke is driven up through the bed and over on the plates or grates. Each ıas 1 or more stokers, depending upon its capacity. Underfeed stokers require ıace and work well even upon poorest grades of coal. They are probably the best r a small or medium-size plant.

t of mechanical stokers, of different types, installed under a 350-bhp :k and Wilcox boiler, ranges from $1 200 to $1 500. In large plants the hoppers are fed from overhead bunkers, receiving coal by conveyers; in ılants it is shoveled directly into the hoppers. Cost of handling coal up to ilers must be considered aside from the stokers for each individual case.

ces for burning powdered coal have long been on the market, but have been ıed. Since pulverized coal can be injected into the furnace in intimate contact with , very efficient combustion can be maintained. The lack of popularity of this is probably due to the objection of plant owners to installing the pulverizing ery and the special feeding apparatus.

nel is too large a subject to be treated fully here. In the numerous successful oil- : systems, the aver boiler effic is much higher than for coal. Conditions essential ess are: all the oil must be consumed before reaching the boiler surface, where tion would be retarded or arrested. Hence, the oil particles must be small, to the duration of burning. The oil spray must be thoroughly mixed with air before

it is raised to the furnace temp; otherwise, combustion will be poor. While fixed baffles facilitate good combustion, they deteriorate rapidly.

The oil is generally heated outside of the burner to about 150° F, to make it sufficiently fluid to flow readily through the supply pipes. In the burner it is atomized, by forcing it through a special nozzle under high press, or by a steam or air jet. Air for combustion is supplied outside the burner.

Gas burners are simpler than those for oil, as gas mixes more readily with air. The injection of a perfect mixture of air and gas may cause difficulty by localizing combustion in the furnace. This is overcome by the system of surface combustion (invented by C. E. Lucke), which permits such mixtures to be burned in a bed of refractory material without visible flame.

12. Superheaters, Economizers, and Feed-water Heaters

Steam superheaters. For the advantages of superheated steam, see Sec. Art 12, 15. Superheaters are placed in the boiler setting, or in a special setting where they are fired as a separate unit. It is generally impracticable to place a superheater in the waste gases from the boilers, because the difference between the steam and gas temperatures at this point is so small that, to transfer enough heat, the area of superheater heating surface would be prohibitive.

In boilers of the Babcock and Wilcox type, the superheater is generally placed under the drum that the gases leaving the front pass flow through the superheater before entering the second pass. In the Stirling boiler it is similarly placed, so that the gases reach the superheater after passing the first section of boiler tubes. In some boilers of the B & W type, but with less space between drum and tubes, the superheater is placed in a separate chamber and heated by by-passing part of the furnace gases. In horiz return-tubular boilers, the superheater is set in the rear connection. Separately fired superheaters either superheat all the steam from a battery of boilers, or only a part of it, as for a particular use, when it is desired to have the remainder saturated. Such superheaters have been built in units of over 3 000 bhp.

Superheaters generally consist of inlet and outlet heads, connected by banks of wrought-iron tubes through which the steam flows. Sometimes 2 or more sections are arranged in series. The tubes of the Foster superheater are protected from injury by the hot gases by C-I rings shrunk on, thus making a surface like that of an air-cooled gas engine. This increases the heating surface, and permits more compact construction.

Cost of superheaters varies widely with the steam press, amount of superheat, gas temp, and type of boiler for which they are used. Aver cost under ordinary conditions is between $2 and $4 per bhp.

Economizers recover part of the waste heat in boiler gases by using it in heating the feed water. They are generally of C-I tubes about 10 ft long, set vertically between headers, and placed in the breeching near the boiler. Each tube has a scraper, which is slowly moved up and down by an outside mechanism to keep the tubes clear of soot and dust.

Economizers show a slight net saving in operating cost. By feeding the boiler hot water they reduce the strains caused by cold feed water, thus saving in boiler repairs. In considering the installation of economizers in a plant operating on natural draft, it must be remembered that the draft will be reduced by friction of the gases through the economizer tubes, and by reduction of temp of the stack gases. Aver cost ranges from $5 to $6 per bhp.

Feed-water heaters heat boiler water by steam, usually the exhaust from engines or pumps. They are made in great variety, but are comprised in two classes, open and closed.

The OPEN HEATER, in which the steam comes in direct contact with the water, consists of a casing filled with horiz trays or pans. Water is pumped in at the top and flows from tray to tray. The exhaust steam fills the entire casing. Advantage of the open heater is that scale-forming solids in the water depusit on the trays, whence they are easily

If the steam contains oil, the feed water must be filtered before going to the
As open heaters are generally run at approx atmos press (the ordinary exhaust
for auxilliaries) the boiler-feed pump must be placed between heater and boiler.
ften requires a second pump to force the water into the heater. The feed pump
ave its suction lower than the bottom of the heater, because water approaching
np of steam at atmos press will not lift to a pump suction. Open heaters are some-
ised under press of live steam, to purify the water when it contains solids which
t precipitate at the temp of exhaust steam. CLOSED HEATERS, in which the water
am are kept separate, consist of a C-I shell forming the steam space, and contain-
es, through which the water is forced. The tubes are either straight or coiled,
eaters using a special form of corrugated tube to facilitate heat transfer. The
re strong enough to withstand the full feed-line press, and the heater is generally
between feed pump and boiler. As the steam does not come in contact with the
oil does not get into the feed, but it often adheres to the tubes and reduces effic of
ansfer. When the water velocity through the tubes is high, there is little trouble
rmation of scales. Such scale as is precipitated is forced into the boiler, where it
and is easily blown off. Scale is difficult to remove from most types of closed heater.
nnecting heaters with exhaust systems, all the exhaust steam is sometimes piped
eater, and what is not condensed escapes to the exhaust pipe or some other heating
. Or, the heater may be connected as a dead end to the exhaust main, the steam
being controlled by the press in the heater.

14. Condensers

cts: to reduce back-press on steam-driven apparatus, and to save boiler water
ood feed water is scarce.

condensers. In these, condensation is effected by bringing the cooling and steam exhaust into intimate contact. Fig 8 to 11 diagrammatically representative types.

g 8, the discharge is directly connected to the suction of a pump, which removes
ted water and condensed steam. The water is sprayed into the steam through a
aped valve, which also adjusts
antity. Fig 9 is the SYPHON
SER, similar to the so-called
TRIC CONDENSER. Instead of
pump to remove the discharge,

Fig 10 shows the KOERTING
R CONDENSER. Water enters

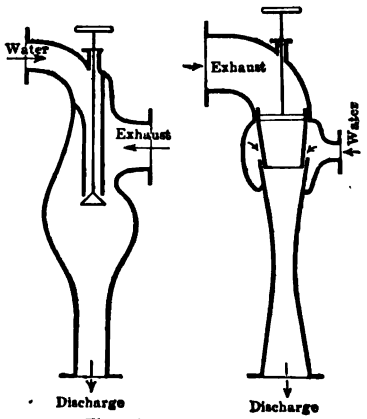

Fig 8, 9. Jet Condensers

nozzle at the top and flows down through the central jet tube. The steam is
ed by contact with the water through a large number of orifices, connecting the
er chamber with the jet tube. The orifices are drilled obliquely, so that the
nters the jet in the direction of the flow and its velocity tends to increase the
of the jet. The largest sizes have a series of water jets. Velocity of the dis-
s sufficient to overcome atmos press, so that neither a pump nor a discharge pipe

tion of high velocity, the condensation may be 6 to 10 lb steam per sq ft per hr. T condensers have maintained vacuums of 25 in of mercury. Loss of cooling water by oration is approx 1 lb per lb of steam condensed.

Cost of condensers varies widely with capacity of the power unit ser vacuum required, and temp of cooling water. Following figures are for com equipments, including cost of installation (1).

Type of condenser	Cost per kw of power unit se
Syphon condensers	$2 to $3
Jet condensers	3 to 4.50
Barometric condensers with dry-air pump	4 to 6
Surface condensers for 26-in vacuum	3.50 to 5
High-vacuum surface condensers	3.50 to 10
Leblanc jet condensers and pumps	2 to 6

Though a separate condenser is desirable for each power unit, the steam saving by condensing will not always offset the fixed charges on the cost of the condens ment, when the power units operate intermittently, or for most of the time at l below the maximum. In such cases it may be profitable to connect to one several power units; as hoisting or rolling mill engines, where all the machines operate simultaneously at full power. Power consumption of the condenser auxil varies from 1 to 10% of the rating of the main power unit.

15. Cooling Water for Condensers

Temperature of condensate corresponds hypothetically to the steam pres the condenser chamber, and in an ideal condenser the cooling water should at the same as the condens Hence, the wt water for co sing 1 lb steam $L \div (t_2 - t_1$ t_1 = temp of ing cooling t_2 = temp of cooling water. latent heat of correspondin and corrected moisture. I sumed that t_3 = temp of densate. Fig shows the rel between wt ing water and of steam cond calculated by a equation. B practice the ence of air raises the ab in the cond

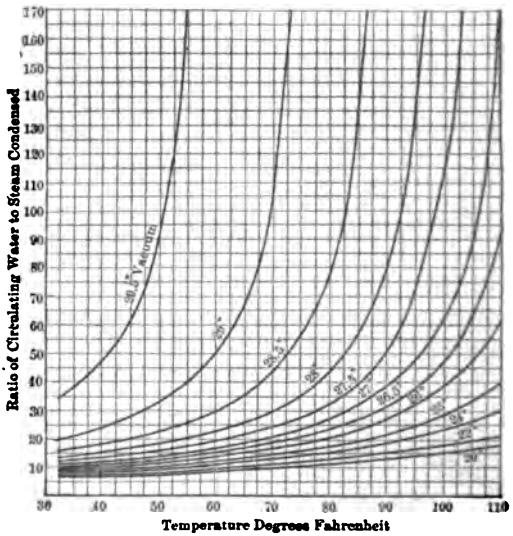

Fig 14. Condenser Water Ratio Chart

above that corresponding to the temp of the condensate.

In jet condensers the condensate and cooling water leave together and at the temp, but in surface condensers the cooling water leaves at a temp lower than

condensate. The chart (Fig 14) may be used to find approx amount of cooling water uired for given conditions, by assuming that the temp of the cooling water is 5 to 10° her than is actually the case. This correction covers the HEAT DROP for ordinary densers. The chart shows graphically how rapidly the cost of condensing equipment s with increase in vacuum. In surface condensers the surface must be greatly in-ased, since the mean temp difference is less, and a greater vol of steam must be handled oth surface and jet condensers. Also, the circulating pumps must be much larger to dle the increased amount of water, with consequent increase in operating cost.

Cooling towers, sprays, and ponds are useful when there is insufficient water the ordinary operation of condensers. The condensing water is cooled for use by bringing the hot water into intimate contact with air. Part of the heat removed by raising the sensible heat of the air, and part by evaporation of ter. Normally, 85% to 90% of the cooling is done by evaporation.

Cooling pond. The governing factor is surface area, depth of water being immaterial. the rate of cooling depends upon air temp, relative humidity, and aver wind velocity, difficult to give a rule for area of cooling pond surface. 100 to 200 sq ft per hp of main am unit are suggested. If there are prevailing winds, it is best to make the pond long narrow, with the long axis perpendicular to normal direction of the wind. Thus the is blown away from the pond, as soon as it becomes warm and saturated and unable do any further cooling.

Spray nozzles require much less space than cooling ponds. They are placed in the m over a pond. Water is pumped to them at 5 to 10 lb press per sq in, and sprayed into air where it is cooled by evaporation and conduction. The spray falls into the pond, ence it is drawn by the condenser circulating pump. Makers state that the water s is not over 2%, and may be less than 1%. The nozzles are from 0.5 to 2 in diam; acity (at the supply press named), 15 to 300 gal per min.

Cooling towers, often of considerable height as compared to their ground area, are ed with some material (as wire mats or wood strips) that will afford large surface area hout seriously impeding the passage of air. The hot water, pumped to top of the er, trickles through the filling. One type of tower is placed on the roof of a building, on an open ground space, and air is allowed to circulate between the wet surfaces. this, the cooling effected is largely dependent on the wind velocity; the size of the tower elatively large. Another type has closed sides and draws its supply of air in at the ttom by chimney action, since the hot moist air within is lighter than the surrounding nosphere. This may be placed wherever convenient, since it is independent of wind rents. A third type uses forced circulation of air, and is the most economical of ice, since the cooling capacity depends upon the volume of air brought into contact h the wet surfaces. Makers state that the power for operating a forced-draft tower bout 3% of the power of the main engines served, for moderate size plants and even s for large plants.

16. Chimneys and Mechanical Draft (7, 8)

Functions of chimneys: (*a*) to provide sufficient draft to draw through grates d fire bed enough air to support the required rate of combustion; (*b*) to carry e gases to such height that they will dissipate without being objectionable.

Design. Intensity of chimney draft depends upon the relative wt of the lumn of gases within the chimney and a similar column of atmospheric air. nce, the design of a chimney depends upon: the temp within and without the imney, barom press, height of chimney, and the physical characteristics of the ses. Having determined the gas velocity in the chimney, a cross-sectional area n be computed which will carry the required volume of gases.

Flow of gases through the furnace, boiler, flues and chimney, may be calculated from clet's formula, $h = (v^2 + 2g)\,[L + A + (BL + C)]$, where h = head producing the w, ft; v = veloc of gases in the chimney, ft per sec; A = coeff of resistance of passage rough the fire; L = total length of path of the gases, ft; B = friction coeff for the rfaces traversed by the gases; C = area of the chimney divided by its perimeter. For dinary conditions, $A = 12$ and $B = 0.012$. Normal stack temp, 450° to 650° F.

Draft, induced or for
forced draft, the air is
air needed to support t
of fire, boilers, and flue

:, or in the breeching. The press at the blower inlet is reduced below atmos press, the atmos press in the ash pit forces the air through the fire and boiler. The chief ntages claimed for induced over forced draft are that combustion is more even and gas press within the boiler setting is always less than that of the surrounding atmos, ice it is unnecessary to shut off the draft when cleaning fires or stoking. On the r hand, there is a considerable loss due to excess air which filters in through leaks ie boiler setting and through the doors, when open. Also, with induced draft, the ers must be larger, as the vol of hot gases is considerably greater, and the cost of ation is higher since power required to drive the fans for the same press-change is :tly proportional to the vol.

eam-jet blowers are generally in the form of a hollow ring, perforated with holes on face. Steam is admitted to the interior and the jets from the holes induce a draft llel with the axis. They are placed at the base of the stack, or in a hole in the ash- rall. They are generally uneconomical for constant service, tests showing that they 5 to 20% of the total boiler steam generated; but, as their cost is low, they may be rable for small plants which can carry their normal load with chimney draft, but h for short periods must meet peak loads far above the normal.

entrifugal blowers of many types, driven either by steam engines or electric motors, : been used. Small propeller fans set in the ash-pit wall, and direct-connected to m turbines, have found considerable favor.

STEAM POWER PLANT DESIGN

17. Factors Governing Choice of Type

)perating cost. The best plant is that which has the lowest total operating t, including fixed charges, while satisfactorily performing the required service. rrating expenses include cost of wages, fuel, water, oil, supplies, and ordinary airs. Fixed charges include cost of administration, interest on investment in chinery and buildings, ground rent of land occupied, insurance, taxes, and reciation. When fuel and labor are cheap it is uneconomical to invest a large n in fuel-saving or labor-saving devices. Cost of power should be figured as cost per actual hp hr, and not be based on the rated power of the plant, as is en done. LOAD FACTOR is the relation between the aver load of the plant for 24-hr day and the load which it is rated to carry. Electric-lighting plants must able to carry a peak load which may not last longer than 1 or 2 hr, and may rate the rest of the time under only a small fraction of the max load; that is, load factor may be only 10 or 15%.

While calculations for a given case may show that fuel-saving devices are warranted steady load conditions, they may not pay in a plant having a low load factor. Hence, leciding upon details of the equipment, the al cost per actual hp-hr delivered must be it in mind. In some cases reliability of vice is so important as to demand an elabo- ion and duplication of apparatus not war- ited by power-plant economics.

Hp of plant	First cost per hp, erected	Annual operating cost per hp
20 to 100	$150 to $200	$70 to $130
100 to 1 000	60 to 160	25 to 70
1 000 to 5 000	50 to 65	15 to 25

The factors influencing the design and op- ting cost of power plants are too numerous discussion here. In the accompanying le of average costs, first costs include buildings; engines for small plants assumed to simple, non-condensing; for medium size, compound condensing engines (or turbines); large plants, turbines. Operating costs include fixed charges, and are based on 10-hr y and coal at $3.50 per ton.

Economy of operation is poor when machines are run far below their rated load; hence, plant should be so chosen with reference to expected load fluctuations that, by throw- some of the machines in or out of service, the others will operate at somewhere near ir most economical conditions.

18. General Arrangement of Plant

While local conditions will decide the detailed arrangement of plant, certain general principles of design should be followed.

Boiler and engine rooms should be separated by a tight partition, to prevent the machinery from dust. Boilers should be connected to the steam main (header) by curved pipes to allow for expansion, and each boiler should have a stop valve between it and the main.

When boiler and engine rooms are side by side, a pipe is run through the dividing wall to each engine, with a valve at its junction with the main besides the stop valve at the engine. It is desirable, though not indispensable, to place a steam separator in the branch pipe just above the engine cylinder. In any case there must be a drain pipe at this point to remove water before the engine stop valve is opened. The above layout permits the use of a comparatively small steam main, since no portion of it carries the total supply for all the engines. When there is more than one bank of boilers, they are generally placed face to face with enough space between them to permit removal of ashes and proper firing. The mains from 2 banks of boilers are usually connected at both ends, forming a rectangle. Valves at different points in the mains allow steam to be turned in either direction, and permit cutting out of sections for repair without interfering with operation of the plant. A further guard against interruption of service is to install a separate steam header for the engines, divided by valves into sections and connected to the boiler mains at 2 or more points. The headers are sometimes in duplicate. When boiler and engine rooms are end to end, more and larger piping is required. Since part of the piping has to carry all the steam and a separate engine main is necessary. To insure continuous service there must be double mains for the engines.

Feed pumps may be in either the boiler or the engine room. They are generally direct-acting, but centrifugal pumps are being more and more used, driven by electric motor or steam turbine. The pumps deliver into a main feed line, with branches to each boiler. A regulating valve is placed in front of each boiler, with check valves in the line before or after the regulating valves. To avoid interruption due to accident, the feed system is sometimes in duplicate. In some plants the duplicate (auxiliary) system is the same as the main system; in others, an injector is connected to each boiler. The exhaust from the plant auxiliaries goes to a feed-water heater. With piston pumps, the heater must be of the closed type to prevent the oil in the pump exhaust from entering the boiler, but with turbine-driven auxiliaries either open or closed heater may be used.

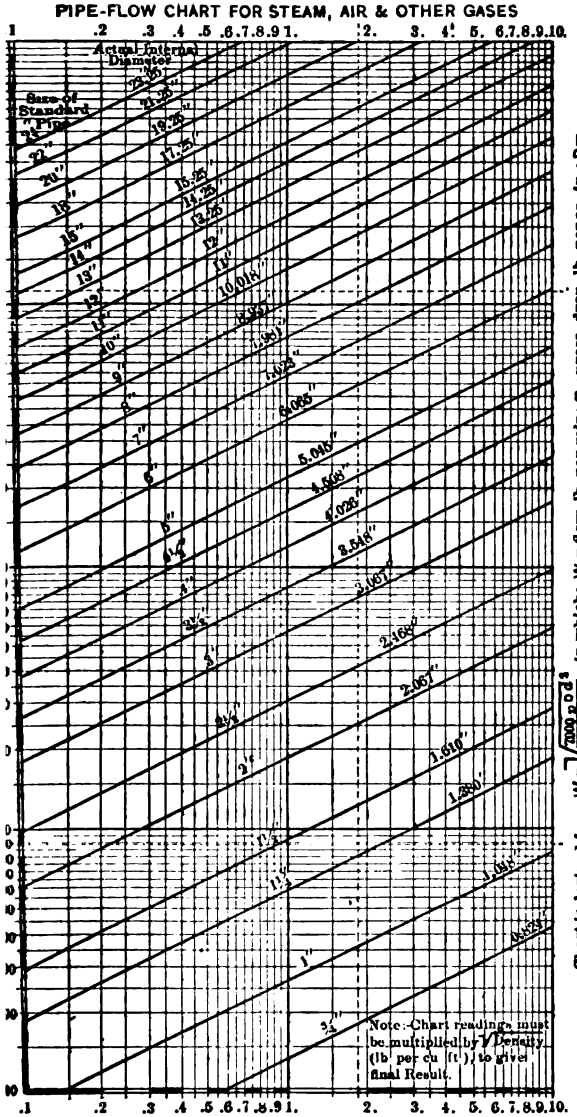
Condensers should be as close as possible to the units which they serve, not only to avoid pipe-friction loss, between engine and condenser, but also to reduce loss of vacuum due to air leakage at pipe joints by minimizing the number of joints. Where space is limited, the condensers are placed below the engine room floor.

19. Steam Piping (For tables of pipes, fittings, and valves, see Sec 41)

Pipe sizes should be properly proportioned to the amount of steam they are to carry. Too large a pipe increases heat loss and initial cost; too small a pipe increases pressure drop due to friction. In the past, 5 000 ft per min was considered the max allowable steam velocity, but the aver in new installations is nearer 10 000 ft, especially when superheated steam is used. Calculation of pipe size on basis of steam velocity is unsatisfactory, since it ignores length of pipe and friction drop. A widely accepted formula for flow in pipes of steam or air is

$$W = \sqrt{\left(7\,000\, p\, D d^5\right) \div \left(L + \frac{3.6\, L}{d}\right)}$$

where W = flow per min, lb; p = press drop, lb per sq in; D = density, lb per cu ft; d = internal diam of pipe, in; L = length of pipe, ft. Fig 15 shows the results of this formula for standard pipe from 0.75 to 24 in diam. In calculating press drop, friction of valves and bends are allowed for in terms of equivalent length of straight pipe. Loss in 1 to 3-in elbows or tees is approx equal to 5 ft of pipe, 3 to



PIPE-FLOW CHART FOR STEAM, AIR & OTHER GASES

Note: Chart readings must be multiplied by √Density (lb per cu ft) to give final Result.
Chart is derived from W = √(2000 p D^5 / L(1+ 4f/D)); in which: W = flow, lb per min; p = press.-drop, lb per sq in.; D = density, lb per cu. ft.; d = internal diam, in.; L = length, ft

Allowable Press-Drop, lb per sq in, per 100 ft length of Pipe

Fig 15. Chart for Flow in Pipes of Steam or Air

5-in = 15 ft, and 5 to 10-in = 30 ft of pipe. Loss in a globe valve is about do that of an elbow.

Expansion joints. Pipes are supported by hangers, floor stands, or wall brac To allow for expansion and contraction, it is best to anchor the pipe at certain p and provide loops or U-bends. Pipe hangers will permit movement by swinging wall brackets should have rollers. Sleeve expansion joints may be used for large p where lack of space prevents long bends. To prevent leaks connections between ea or boilers and steam mains should always have long bends (or their equivalent

Drainage of steam pipes. To prevent dangerous accumulation of condensa pipe lines should have a slight slope in the direction of flow, so that the water will to the drainage points even if the steam velocity be high. Openings at drainage p should be wide, so that the water will not cross them even when carried along at velocity; they are connected with a chamber large enough to hold considerable conde tion. For small and medium-size pipe, DRAINAGE CHAMBERS are best made by conn ing to a tee in the line a short drop leg of the same size pipe. These legs are capped blank flanged at the bottom, with water gages at important drainage points. Drai chambers are connected to a STEAM TRAP, for removing condensation without allow leakage of steam. Each trap has a by-pass around it, normally closed by a valve the trap fails to work, the water may be drained through the by-pass. Traps can be depended upon to drain a cold line; the by-pass should be opened when steam being turned on. Condensed steam ("drips") may be returned directly to the boile it is from a high-press main, or to the hot well or open feed-water heater. Valve steam lines over 6 or 8 in diam should have a small by-pass around them. Steam through this allows the line to be warmed gradually; also, large valves are difficult open unless the pressure on both sides is equal. Large valves often include a by-pas

RECIPROCATING PUMPS

20. Classifications (17, 18, 19, 20)

Water-end classification comprises the simplex pump, having a single wa cyl, duplex, with 2 water cyls in parallel, and triplex, with 3 water cyls in paral The pump is single-acting when it takes water on one side of the piston only double-acting when it takes water during both strokes.

The water cyl has a piston (bucket) or plunger. A piston makes a loose fit in the and is packed with hemp or a metallic packing ring (Fig 16). Piston-and-ring p (Fig 17) is a cheaper construction, but is apt to score with gritty water. Both types permit undetected leakage past the piston. They may be used for heads up to 150 lb per sq in. For pressures of 150–300 lb, outside-packed plunger pumps (Fig 18, 19) are recommended; for pressures exceeding 300 lb they are necessary. With outside packing leakage is readily detected, and stopped while the pump is running. Scoring (cutting) of the plunger is also plainly visible. Plunger pumps cost more than piston.

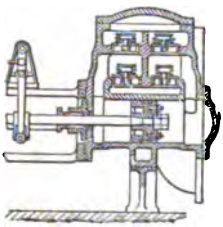

Fig 16. Water End of Piston Pump

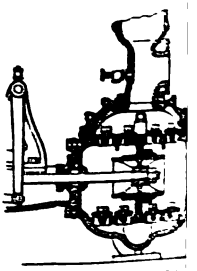

Fig 17. Piston-and-Ring Pump

When both suction and discharge valves are above the barrel (Fig 16, 18), the pump of the submerged type; when the suction valves are below (Fig 17), it is of the straight-way type. Submerged type is used for hot liquids and condenser service, the pump being surrounded by cool and de-aerated water, which protects the packing and keeps

action. But, as the flow of water in the cyl is reversed at every stroke, it is not ended for strokes over 14 in. Straight-way type costs more, but the water has direct flow through the and is therefore used for ater velocities.

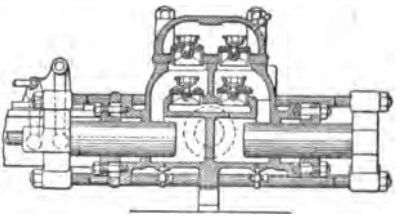

Fig 18. Outside, End-packed Plunger Pump

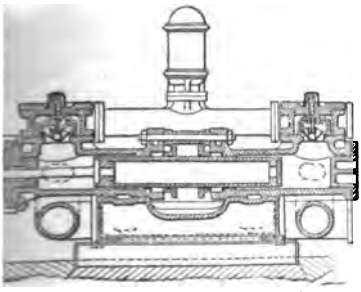
am-end classification. s are divided into simple, und, and triple expan- ccording as each water served by a single steam high and low-press cyl, high, intermediate, and ess cyl.

mmercial classification: ARLY-FITTED pump has a C-I plunger or piston working in a bronze ring, or sleeve; piston rod is of steel, and valve seats, springs, and all inside bolts ts, are of bronze; valves are of rubber or bronze. BRASS-FITTED. Besides onze of regularly-fitted pumps, the rods are of "tobin bronze," piston is solid bronze or bronze-lined, and stuffing-box throats and glands are bronze-lined. In ALL-IRON FITTED pumps, for ammonia or tar, no bronze nor brass comes into contact with the fluid pumped. Valve seats are of malleable iron, springs of steel, the C-I piston works in the solid-bore of the cyl, and plunger nuts are iron. ALL-BRONZE pumps, for acids that attack iron, are entirely of bronze, which in some cases must contain no zinc. LEAD OOD-LINED pumps. Large pumps, that would be too costly if of bronze, made of iron, with the whole interior lined with an acid-resisting material, , wood, or cement. By LARGE OPENINGS is meant that the valve seats are tructed by ribs. Ball or clack valves are of this type.



19. Outside, Center-packed Plunger Pump

ecial-fitted" pumps for different liquids:

r fitted"	Liquid pumped	"How fitted"	Liquid pumped
.....	Ammonia	Regularly-fitted.....	Calcium brine

.....	Calcium chloride	" "	Citric acid
.....	Caustic soda	" "	Cyanide of potassium
tted.....	Brine	Lead-lined, no zinc...	Hydrochloric acid
"	Copper liquors	" " " " ...	Hydrosulphite acid
"	Glycerine; oils	All-bronze, or lead or wood-lined C-I, no zinc	Sulphuric acid
" (large ngs)	Sewage		

ıp size designations: For direct-acting pumps, 8 & 5 × 12, means 8-in cyl, 5-in water cyl, 12-in stroke. For pumping engines, 5 000 000 gal per eans that the pump's normal capacity is 5 000 000 gal in 24 hr. For a ugal pump, 6-in, single, 2 or more stages, means that the discharge pipe is am and that there are 1, 2, or more impellers.

21. Reciprocating Pumps, Design and Construction (17, 19)

Head. — Total head pumped against = $h_s + h_d + [(v_d^2 - v_s^2) \div 2g] + d$ where h_s = suction head, ft, measured by gage on suction side of pump; h_d = disch head, ft, measured by gage on column pipe; v_s = veloc, ft per sec, in suction at gage point; v_d = veloc, ft per sec, in discharge pipe at gage point; d = dist between gage centers, ft. SUCTION HEAD h_s = pipe entrance head lost + $v_s^2 \div$ pipe friction (including bends) + suction lift. DISCHARGE HEAD h_d = static head a pump + friction head in pipe line (including head lost in valves, elbows, etc).

Suction head. Suction action of a pump is produced by atmos pres surface of water in the pump well or sump, which forces the water into the p chambers after the plunger has created a void in them. Theoretical w column sustained by atmosphere at sea level is 33.9 ft, but this is not obta because under rea press water boils at than 212° F, and tains about 2% si solution, which is d ated. The theore value is also red by air leakage friction, and water locity. Fig 20 s suction lifts at var temps, based on a s suction pipe and bend, at a water v of 3 to 4 ft per Long suctions, or b and foot valves other obstructions in the pipe, reduce the actual lift. Fig 20 shows that if water is hotter than 160° F, it must flow to the pump under press. T liquids must also flow to pump under press.

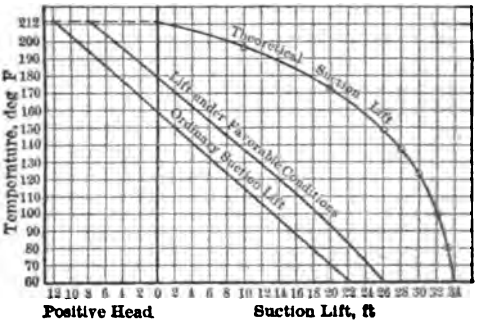

Fig 20. Suction Diagram

Air chamber, generally of C I, is attached to the discharge pipe. When on the tion pipe it is called a VACUUM CHAMBER. It is to provide an elastic element in the line, taking up shocks and inducing a uniform flow. Air chambers are essential in the single-acting, duplex single-acting, and crank-and-flywheel pumps, but may be omitted in other types. Volume of the air chamber should be 6 to 8 times the displacement simplex direct-acting or crank-and-flywheel pumps and 3 or 4 times in duplex pumps. When air chambers are used, they should have a gage glass and means provided to charge them with air when the water in them rises above the proper height. Vacuum chambers are placed on the dead end of a tee REPLACING AN ELBOW in the suction line. Air liberated from water during the suction period enters the vacuum chamber until it has displaced all the water; air will then enter the pump as if there were no vacuum chamber.

Cavitation. At excessive piston speed, the water is drawn from suction pipe faster than atmos pressure can force the water into it. Hence, a break occurs in the water column, known as CAVITATION. This may also be caused by liberation of air and vapor from water under a high suction head. Cavitation is more apt to occur at high temp, high lifts and high suction heads than with low suction and low temp.

Capacity and speed. Relation between capacity and cyl diam of pumps is given by $G(1 + \text{slip}) = 0.0408 d^2 P$

where G = gal per min for 1 double-acting plunger; d = diam of plunger, in; P = piston speed, ft per min. This is for a simplex, double-acting pump. For single-acting pump divide the right-hand member by 2, and for a duplex double-acting pump multiply it by 2. As the duplex pumps usually do not make

ıke, the formula applies only to the rated stroke. Actual stroke = 0.7 — 0.9 ated stroke. An allowance is necessary for the volume occupied by the pis- rod. It is often made by increasing the slip (see below) by 1 or 2%.

Pump efficiency is $E_p = \dfrac{\text{Wt of water pumped} \times \text{total head}}{\text{Ihp of steam end}}$ (3)

c depends upon piston speed and stroke; its value is shown in Fig 21, plotted inst the length of stroke. Speeds generally used with different strokes are shown.

For pressure and wet-vacuum pumps use 80% of values given for boiler-feed pumps, 60% of values)
Rev per min
Piston speed, ft per min
Pump effic, %
Rev per min
Stroke in Inches

Fig 21. Speed and Efficiency of Pumps

ote. — Data on which Fig 21 is based are from tests of commercial pumps. Piston d depends upon length of stroke and number of strokes per min. For boiler-feed pumps, taken as 0.5 that of ordinary service pumps, to allow for sudden capacity demand. triple-expansion pumps, it may be taken 10% higher, because stroke is long and a heel is often used. For pressure and mine pumps, where high water velocity is not rable, and in wet-vacuum pumps, where a high velocity in the system would break water seal at the valves, a piston speed of 80% of ordinary service speed is taken.

Pump slip is the shortage in delivery, due to loose-fitting or worn piston, cyl, valves, and failure of valves to close promptly as stroke reverses. Expressed % of piston displacement, and based on Eq 2:

$$\text{Slip} = \left(1 - \frac{\text{Gal per min delivered}}{[0.0408(d^2 - d_1^2) + 0.0408\,d^2]P}\right) \times 100 \qquad (4)$$

re d = plunger diam, in; d_1 = piston rod diam, in; P = piston speed, ft per . Slip is 2% or less in new pumps, with water reasonably free from air, and arge pumps may be even 0.5%. For calculations it is often assumed as 3%. nps showing 5–10% slip are in poor condition and should be overhauled.

Water velocity in the suction pipe of reciprocating pumps should not exceed ft per min; in valve seats, 220 ft per min; in discharge pipe, 300 ft per min. ; = gal per min, pipe diam is found as follows:

$$\text{suction diam, in} = \sqrt{0.1\,G}; \quad \text{discharge diam, in} = \sqrt{0.08\,G} \qquad (5, 6)$$

alve construction (17). For low heads, and where tightness is essential, e are of soft rubber; for heads up to 75 lb per sq in, medium hard rubber; up to 1

medium hard rubber or bronze; up to 300 lb per sq in, leather-face, conical-wing or flat seated metal valves are used. Hot water requires special rubber composition and for heads of 300 to 3 000 lb per sq in, conical-seated bronze valves are used. Thickness of a rubber valve depends on the unsupported opening and Eq 7 serves as a guide.

$$t = 0.05\, s \sqrt{p} \qquad (7)$$

where t = thickness, in; s = greatest unsupported span, in; p = water press, lb per sq in

Valve-spring pressure depends upon water press. Approximate rules are:

(*a*) Discharge valves. Spring pressure, lb per sq in on valve area = 0.5 to 1% of the discharge press; max, 5 lb per sq in.

(*b*) Suction valves. Spring pressure on valve area = 0.25 to 0.5 lb per sq in, if the water is lifted by suction; for pressure suction, 0.5 to 1 lb per sq in.

Valve area. If A_v = valve-grid opening area, sq in; V_v = veloc through valves (= 220 ft per min); A_p = piston area, sq in; V_p = piston velocity (= 100 ft per min

$$Q = A_v V_v = A_p V_p; \quad A_v = 0.45\, A_p \qquad (8)$$

that is, valve-grid opening area is 45% of piston area for general service. 50 and 60% valve area is often demanded in water works specifications, and pays for itself in good service and durability. (Above velocities are assumed.) Largest size valve for good service is considered to be 4.5 in. Clear opening of valve seat will be 50 or 60% of disk area.

Valve lift. Assume discharge head = 200 lb per sq in, water end 12 × 18, with 4-in valves and 45% valve area.

$$\text{Number of valves} = \frac{\text{Required valve area}}{(\pi 4^2) \div 4 \times 0.6} = \frac{A_v}{7.52} = \frac{0.45 \times (\pi 12^2) \div 4}{7.52} = 7 \text{ (approx)}.$$

From valve-spring pressure rules (above), the spring tension = 0.005 × 200 = 1 lb per sq in, which equals 2.3 ft, and $v = 8.02\sqrt{2.3} = 12.2$ ft per sec = 729 ft per min. Then from Eq 8.

$$\text{Area valve opening} = (V_p + V_v)\, A_p = (100 + 729)\, 113 = 15.5 \text{ sq in.}$$

Total periphery of seven 4-in valves is $7 \times \pi 4 = 88$ in, and lift = 15.5 ÷ 88 = 0.176 in (say 3/16 in); and allowing for a coeff of contraction of 0.5, the lift will be 3/8 in. Hence spring load on the 4-in valve, when raised 3/8 in, is [(π × 4²) + 4] × 1 = 12.6 lb.

Pressure-pump valves should be of metal, with conical seating surface, which can be ground to a perfect seat more readily than a flat surface. But, to pass same volume of water, they must lift 45% higher than flat valves. Pressure valves should be guided to a perfect seat. One method is to have on the under side of valve disk 3 or 4 guide wings. For impure mine water, a flat-seat, leather-faced wing valve is used.

Structural formulas for water end: $d \times p = 2\, t \times s$; t (for cyl heads) $= 0.1\, d \sqrt{\frac{p}{200}}$

$B = d + 2\,(b + \frac{1}{4}$ in); $f = b + \frac{1}{4}$ in; $D = B + 2\,(b + \frac{1}{4}$ in), where B = diam of bolt circle, in; b = diam of bolt or stud, in; D = diam of flange, in; d = diam of cyl, in; f = minimum thickness of flange, in; p = internal press, lb per sq in; s = allowable stress of metal, lb per sq in; t = thickness of metal, in.

22. Pump Tables, Duty, and Steam Consumption (19)

Water head vs steam pressure. The head under which a pump will work depends upon the relation, $P_s A_s \times E_p = P_w A_w$; where P_s = steam press, lb per sq in; A_s = steam piston area, sq in; E_p = pump effic (see Fig 21); P_w = water press, lb per sq in; A_w = water piston area, sq in.

By transpositions of this formula can be found the proportions of steam and water cylinders for different steam pressures and heads. When steam press is increased for pumping under a greater head, the required structural strength of cyl and cyl heads must be determined. For a given vol of water, the dimensions of water end depend on piston speed and head pumped against. Thus, Tables 9, 10, 12, 13 show several different water and steam cyl for the same length of stroke. These tables are of end

ntially the same as built by a number of makers. Larger sizes are obtainable on spe-ation, or, when very large, are built to order.

Priming and operation. To facilitate starting, steam should be pu
the pump with water and to prevent it from acting as an inspirator
the discharge pipe filled, there is no danger of knocking out the head
pump up. If the suction pipe has a foot valve, the pipe may be
steam to fill it and the pump chambers, and drive out the air through
or ¾ the size of the discharge pipe plus 0.5 in. to
chamber. If there is no foot valve, each chamber
a pressure supply. Another mode of priming is to
valve provided with a stop. Check valve is
stroke and closes on suction stroke. The
chamber. Drain cleaning opening to the cyl.
and bar steam end.

Operation. The Test Committee of
" means the lift of

water pumped × head) per million B t u supplied. The definition of duty viously used by pump makers, who naturally wish to make the best show- for their product, was the ft-lb of work per 1 000 lb dry steam. The duty nputed according to the committee's recommendation may give results as ch as 8% lower than on the old basis. Hence, the definition of duty should specified when using the term.

For compound condensing steam end, cyl non-jacketed but lagged, with 6 lb bac press, the card duty is the same as for compound condensing cyl. Steam effic is 5 lower than above, and total effic is 4% lower. That is, the actual duty is found by tak the card duty above (for example, 91.0 for 70 lb press, and 12-in stroke) and multiply it by total effic less 4% (45 − 4 = 41 for 70 lb press, and 12-in stroke). Hence, du = 91 × 41 = 37.4. Steam consumption in this case is found by dividing the steam co sumption (for example, 48 lb for 70 lb press and 12-in stroke) by the new total effic and multiplying by the total effic as above, 45. Hence, 48 × 45 ÷ 41 = 53 lb.

Steam effic, as used in the tables, accounts for press lost in wire drawing, steam lo by leakage condensation, etc. Slow-speed, triple-expansion steam ends, equipped a outlined above, give duties of 12 to 15 million ft-lb per 1 000 lb dry steam less than stat in the table. Tables are for pumps in good working condition and operating at norma length of stroke.

Cost of reciprocating pumps. Some costs of general service pumps, sinkin pumps and station plunger pumps for mine service, are given in Tables 4, 12 For cost of large or special pumps, apply to makers.

CENTRIFUGAL PUMPS

23. Classification

Turbine pump. The IMPELLER vanes are encircled by stationary distributing vanes discharging into the spiral casing, to convert velocity head into pressure head. In VOLUTE PUMPS, the impeller discharges direct into the casing. Effic of recent designs is improved by a "whirlpool chamber," between impeller and outer spiral casing. Centrifugal pumps comprise SINGLE-STAGE, for low heads, and MULTI-STAGE, for high heads (Art 24). Multi-stage pumps comprise a series of impellers on a common shaft, each having its own casing. Each impeller delivers water with an added increment of head to the following impeller, the last one delivering into the discharge pipe at required head.

If, viewed from the power end of impeller shaft, the rotation is clockwise, the pump is right-hand; if anti-clockwise, it is left-hand.

24. Structural Relations (21, 22, 23)

Capacity, water velocity, and size. Capacity is closely related to size and speed. Water velocity at the discharge flange varies between 8 and 10 ft per sec in American pumps, and 6 to 8 ft per sec in European. By a pipe reducer the velocity is brought down to 3 to 6 ft per sec in the pipe line. With given capacity and above velocities at the discharge flange, the diam of discharge pipe and size of pump are found.

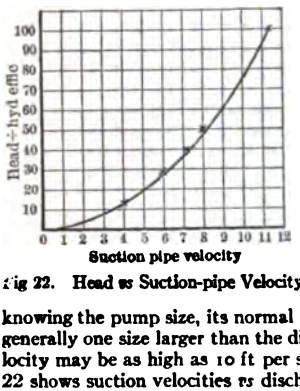

Fig 22. Head vs Suction-pipe Velocity

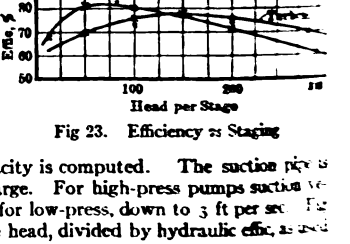

Fig 23. Efficiency vs Staging

knowing the pump size, its normal capacity is computed. The suction pipe is generally one size larger than the discharge. For high-press pumps suction velocity may be as high as 10 ft per sec; for low-press, down to 3 ft per sec. Fig 22 shows suction velocities vs discharge head, divided by hydraulic effic, as used in design work.

Efficiency is a maximum for the normal or rated head and discharge. Fig 23 shows that normal head per stage for volute pumps should be less than 130 ft;

urbine pumps, less than 225 ft. For single-stage pumps, the best effic is l at one speed only. For speeds above and below the best, effic is slightly than the maximum; that is, there is a speed where the sum of water friction earing friction is a minimum (Fig 24). For a homogeneous series of pumps

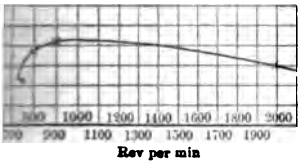

Fig 24. Efficiency *vs* Rev per Min

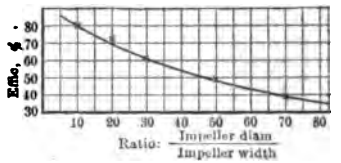

Fig 25. Effic *vs* Ratio of Impeller Diam to Width

re the areas and dimensions of one are proportional to those of any other), fic increases with capacity; that is, the water friction is proportionately less ger pumps.

: greater the speed the higher the effic for a given head and discharge, until the s reached; because the ratio of diam to width of impeller becomes smaller. But, if e carried too far to secure speed, certain desirable features in design must be sacrificed 5). Effic varies with specific (Fig 26). For good effic high heads, the volume de- l should be not less than 75 r min. For STAGED PUMPS, tages of less than 130 ft, the type gives the better effic; stages are greater than 130 e turbine pump is superior 3). For a discharge of less than 600 gal per min, the turbine pump gives the better for larger capacities, the volute (Fig 27).

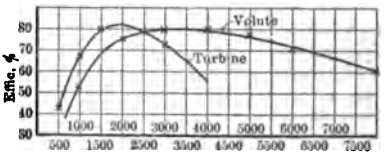

Fig 26. Effic *vs* Specific Speed

above statements refer to the head developed by a single stage, not the total head ulti-stage pump. If the specific speed is unfavorable to good effic, the conditions e improved by using several stages.

ripheral speed of an impeller is approx determined by the head, and in the peripheral speed determines diam and rev per min. Small diam and high rotative speed give a low-priced driver, but the peripheral speed might give a higher head than desired (as in case of a direct-connected steam turbine without velocity or pressure staging). There would also be danger of cavitation in the suction pipe. Suction-pipe velocity should not exceed 12 ft per sec rably 6 to 8 ft). But, the speed must not be so low in proportion to eral speed that the water may slip back through the impeller, as when w-speed engine is direct-connected to a small pump. In good design, eral speed may reach 90 ft per sec, and rev per min may vary from 4 000; but both are sometimes higher. By staging, high heads and iable speeds (commercial speeds of electric motors) may be adopted ut cavitation and vibration.

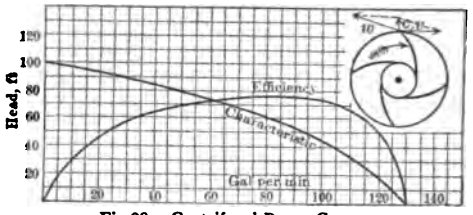

Fig 28. Centrifugal Pump Curves

Pump characteri These are the head-c city curves when th pacity coordinates horiz. Pumps ar signed with falling and rising character Fig 28, 29, 30 giv cal curves for the m shapes shown in t of each cut. In the peller shapes, v = v veloc of tip of vanes

veloc of water relative to that of vane; c = absolute veloc of water leaving in The angle between v and w varies with shape of vane.

Short relations for centrifugal pump calculations. The approx size pump for a given capacity is found by:

$$Q = Ac = (\pi d^2)\, c \div 4 \times 144, \text{ where } c = K\sqrt{2gH}, \text{ and}$$

$$\text{Gal per min} = K_1 d^2 \sqrt{H}, \text{ whence, } d = \sqrt{\text{Gal per min} \div K_1 \sqrt{H}}$$

where A = discharge-flange area, sq ft; c = velocity at discharge flange, ft sec; d = discharge-flange diam, in; K = experimental factor in $c = K\sqrt{}$ $K_1 = (\pi K \sqrt{2g}) \div (4 \times 144 \times 449)$; H = total head pumped against, ft.

Proper pump speed for best economy is determined by the pump size and head; pump size fixes the impeller diam within a small limit and the b with the pump characteristic, fixes the speed. The relation between sp diam, and head is

$$v = \pi DN \div 12 \times 60 = \phi\sqrt{2gH}; \quad \text{whence } N = (\phi\, 1\,840\sqrt{H}) \div D$$

where v = peripheral velocity of impeller, ft per sec; N = number rev per min; D = impeller outlet diam, in; ϕ = experimental factor; H = total head, ft.

The following relations are true as long as ϕ is constant for a homogeneous series of pumps (that is, a series in which each impeller is merely an enlargement or reduction of another having the same proportions): H varies with N^2; rev per min vary with $\sqrt{H}$; gal per min vary with $\sqrt{H}$ and with N; hp in the water pumped varies with $H^{3/2}$ and with N^3. The brake hp input does not vary as $H^{3/2}$ or N^3, because effic varies with pumps of different size of the same series; that is, friction loss in glands and bearings is not a fixed percentage the input for different size pumps.

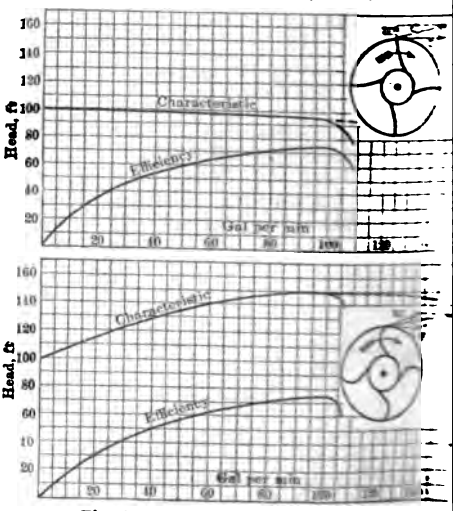

Fig 29, 30. Centrifugal Pump Curves

cific speed, defined as the rev per min at which any impeller of a series would run ere of a diam to discharge 1 gal per min against 1 ft head, is $N_s = (N \sqrt{\text{gal per min}})$ $^{3/4}$. This expression involves the head, gal per min, and speed, which are essential cting a centrifugal pump, and which effect the effic, as shown in Fig 23 to 27. It only practically constant for a single impeller at any speed, but for a whole series of lers of homogeneous design. Thus, specific speed is an index to type; it varies en 500 and 8 000.

25. Performance of Centrifugal Pumps (22, 23)

r single-stage, the usual limit of head is 100 to 150 ft; in rare cases, up o ft or more. Generally, for heads over 150 ft, staging is adopted, and can ntinued up to any head within the limit of strength of pump and pipe. bles 15, 16, furnish examples of approx centrifugal pump performance.

ble 15. Standard Type "*S*" Centrifugal Pumps (Allis-Chalmers M'f'g Co) = pump size (= diam of discharge); *B* = rev per min; *C* = hp of driving motor

For higher heads, multi-stage pumps gives best effic

te. — Figures above the stepped line are for 60-cycle motor speeds; those below, for engine speeds. *C* should not be used to find the pump effic, it merely indicates the r commercial size of motor.

Lines of standard side-suction centrifugal pumps are made for heads fr 20 to about 180 ft, and capacities from 30 to 500 gal per min, operating at cycle motor speeds. For heads above 110 ft and capacities below 150 gal min, small multi-stage or 2 pumps in series, are recommended. Boiler-f pumps of from 2 to 6 stages, driven by motor or steam turbine at 1 750 rev min, are made for press of 150 to 250 lb and capac of 200 to 1 250 gal per m

Table 16. Multi-stage Centrifugal Pumps, 60-cycle, Motor-driven (Allis-Chal

	Rev per min	1 160	1 160	1 160	.....	.....	74

Example. To find approximately a pump and motor to deliver 720 gal per against a head of 380 ft. Table 16 shows this capacity to be within the limits of pump, of either 3 or 4 stages, running at a motor speed of 1 750 rev per min. To the hp, use formula: $\text{Hp} = \frac{\text{Gal per min} \times \text{head} \times 0.000253}{\text{Effic}} \times K$, where $K = 1.1$, a const to take care of the small over-capacity which the pumps are designed to give.

$$\text{Substituting, Hp} = \frac{720 \times 380 \times 0.000253}{0.61} \times 1.1 = 125.$$

28. Construction Details and Costs (21)

Casings are usually of C I; for high press, they may be of steel. Liners be used to with acid action or abr Casing is of either s barrel type. Sp ing divides the and bearing housi the horiz plane shaft. This pr ready access to the interior, as the pi nections are in the half of the pum need not be di Barrel casing has movable side pla 31, No 14) at the fo end, so that the im and separators m slipped out of the ing, for disassembl pump. The barrel type is the cheaper to build. Fig 31 is a section of a typical bronze-fitted pump.

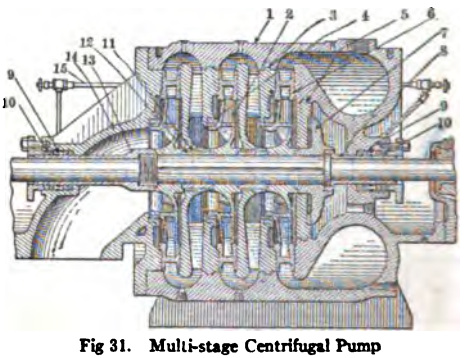

Fig 31. Multi-stage Centrifugal Pump

The bronze wearing ring (Fig 31, No 4) prevents leakage around the runner thro

be a loose-running fit, or fitted to the impeller, with a small clearance between d casing. The clearance must not be too small, else vibration or end play of shaft bring the surfaces in contact. The water-ring seal in the packing (Fig 31, No 9) t- air from leaking into the suction. The flange coupling to motor should be made by boring the bolt holes large and providing rubber bushing.

thrust. Impellers, even when placed back to back, have an unbalanced thrust the suction, which must be resisted. It may be taken up mechanically by a hrust-bearing. The balancing disk (Fig 31, No 7) is of the hydraulic type. High- ater leaking past the shaft presses against the disk and pushes the impellers and o the right. This slightly opens the leakage joint at the disk periphery, allowing of water faster than it leaks past the shaft; thus reducing the press against the d allowing it to move to the left. Then the leakage joint is closed and the cycle es until the disk is in equilibrium. Hydraulic balance is obtained by these means, ails varying in detail in different makes of pump.

r space occupied by a centrifugal pump and its driver is less than that for a cating pump, including its power end, except in sizes having a 3-in discharge and , where the reciprocating pump has the advantage.

of a centrifugal pump is affected not only by the size or capacity, but head pumped against, speed, number of stages, quality of construction, mmercial conditions.

Table 19. Average Cost of Iron Single-stage Pumps

ty. r	A	B	C	D	Capacity, gal per min	A	B	C	D
	$ 55	$ 80	$150	$200	1 500	$290	$420	600	$700
	90	135	200	250	2 000	340	500	710	790
	150	215	335	400	5 000	660	900	1 190	1 300
	220	325	510	580	10 000	1 300	1 900	.....	.....

— *A* = **low-head** pumps, with iron impellers, single suction, belt-drive, and no **ance guarantee.** *B* = double-suction pumps, belt or direct-drive, but otherwise o *A*. *C* = **pumps** of better construction and heads up to 150 ft. *D* = pumps **good construction,** suitable for direct motor-drive.

of 4-in, single-stage pump. Single-suction: iron, $100; brass impeller **ss sheathed** shaft, $160; bronze ditto, $212. Double suction: iron, **brass impeller** and brass sheathed shaft, $250; bronze ditto, $350.

Cost of 2-stage pumps is about 3 times that of single-stage, for same charge and speed, but double the head. As the number of stages increases cost approaches the number of stages times the cost of a single-stage pump.

For similar conditions of head, speed, and construction, cost varies dir as capacity. Water-supply pumps cost about $1 000 per million gallons capacity (DeLaval Steam Turbine Co).

For pumps suitable for high heads (as for mine drainage), the design is sp and cost varies widely. Examples:

2 500 gal per min	600-ft head	$ 5 000
5 560 " " "	280-ft "	26 000
5 500 " " "	300-ft "	27 800

Cost per lb wt is nearly constant, decreasing slightly as size of pump incre for small iron pumps, about 20¢ per lb; higher for brass and bronze-fitted

27. Installation and Operation (24)

Location. Pumps should be accessible, set on rigid foundations, with base sli above the floor. Care must be taken in setting, not to exceed proper suction he (including losses in suction pipe or fittings). If bolted to foundations instead o grouted in, the base must be in perfect alinement when drawing up on the bolts.

Lining up. In setting the pump, see that its shaft is alined with that of the dri This can be done by putting a steel scale on the coupling flanges. If the machine is up correctly, the scale will rest on both flanges all around the surface. Also see that clearance between the 2 half couplings is equal at all points of the circumfere If bolts instead of grouting are used, make sure after the bolts are tight, that the pu and driver are still in line.

Piping. Piping should have as few bends as possible, and these should be of radius. Introduce no unnecessary bends or other sources of friction in the suction Suction line must be free from air leaks, especially where it is long, or the pump is at height above water level. Avoid air pockets in the suction line; if any exist, pro means to get rid of the air.

Check valve. In multiple-stage and in single-stage high-press pumps, a check v should be placed in the discharge line. This should be put between gate valve and pu Where there is a foot valve and possibility of water hammer, the discharge valve sh be closed before shutting off the power for stopping the pump.

Foot valve. Where the suction lift is not high, a foot valve is often advisable simplifies the priming of the pump. There must be a strainer to keep the foot va becoming choked by foreign substances. A foot valve is not advisable for a pump against a high static head; on shutting off the power, the pump would stop and the water rushing back might close the foot valve before the check valve could producing heavy water hammer. The foot valve should be of flap type, and of size to minimize friction.

Bearings must be cleaned before starting the pump for the first time, as dirt foreign substances may get in during shipment or erection. They should then be with pure, clean mineral oil, which must be changed when it becomes dirty and the bea thoroughly cleaned at same time.

Stuffing boxes and packing. Before starting the pump, the stuffing boxes should carefully cleaned and packed. There must be enough packing back of the water ring so that the inlet water for sealing is brought in at the ring and not at the pa Piping supplying the water seal should fit tightly so that no air can leak in; air entering at this point might cause the pump to lose its suction. If the water is dirty, or gritty, the sealing water must be obtained from some clear source. The valves for the water seal must be open before starting up.

If packing is too tight, it may cause burning of the packing and cutting the s Packing-ring joints should be at angle of 45°, and the joints of the several rings should be staggered. On starting the pump, it is better to have the packing a loose (without causing an air leak); instead of putting too much pressure on

heavy oil in the gland until the pump works properly and then gradually tighten and. Since packing boxes are water sealed, see that the valves are open before ig; a slight leakage of sealing water through the gland is desirable.
in water may be liberated and collect in the pump passages. Hence, the air cocks) of the casing should be opened occasionally; or, if much air, these vents may be artly open during operation, connecting them to drain pipes if desired. If the ty falls off without apparent reason, it is well to open the pump and examine its r and the impeller passages, as pieces of wood and other foreign bodies are sometdrawn into the pump.

ning. Unless the water supply flows to the pump with sufficient head to fill the , the pump must be primed. PRIMING BY EXHAUSTER or ejector is convenient steam or compressed air is available. The discharge pipe must have a tight valve o the pump, to allow the air to be exhausted from casing and suction line. A foot s desirable in connection with a steam exhauster, for priming the first time, or when, reason, the suction line has been emptied. PRIMING BY FOOT VALVE can be done there is a supply of water available under pressure, by merely allowing the suction nd pump casing to fill. All pet cocks should be opened during the filling to allow of air. PRIMING BY VACUUM PUMP. Where steam is not available and it is imable to fill the suction line with water, a hand or power-operated air pump may be A valve must then be placed on the discharge line.
riming multiple-stage pumps, the air must be exhausted thoroughly from each if primed by exhauster, it should be connected to each stage.

ting. The pump casing must be entirely filled before starting; if run empty, arance rings and shaft sleeves, which have very small clearances, will bind, heat, t. When first starting the motor, be sure that its direction of rotation agrees with the pump; pumps must not run in a direction opposite to that for which they are d. This is usually stamped on the casing. After the pump is primed, the shaft be turned over 1 or 2 rev, to allow all air to free itself from the impeller vanes.

WATER TURBINES

ssification. *A*. According to the action of the water: as (*a*) reaction turbines h the water is under press in the runner buckets, the energy being derived by ge the path of the water in passing through the runner, or by the reaction of the n the restricted bucket discharge opening; (*b*) impulse turbines in which the rmation from potential to kinetic energy takes place in the guide apparatus, and ter is received by the runner at the full veloc due to the head. *B*. According to n of flow of the water through the runner: as (*a*) radial flow (outward or Fourneyard or Francis turbine); (*b*) axial flow (Jonval type if reaction, Girard, if impulse); ed flow (American, in which flow is first inward radial and then down parallel); gential flow, where the jets strike cups on the periphery (Pelton and spoon wheels). ording to whether the shaft is horiz or vertical.

ripheral veloc of runner, ft per sec	
riph veloc of runner + veloc of jet	

ut available. $P = (QH + 8.8) \times E$; when $E = 80\%$, $P = QH + 11$.

Velocity of water (25). HEAD RACE. In low-press plants, as little head as possi should be lost through friction and eddies. Water is led to the turbine in an open cha at a low veloc, never exceeding 2 ft per sec. In the TURBINE PIT or flume, the veloc may be even lower, to avoid eddies on entering the guides. Head-water level must not be less than 1.25 diameters above guide-vane openings; otherwise air may enter as eddies, and destroy suction action in the draft tube. If this rule can not be observ eddies may be reduced by placing wooden floats in the head race just above the turbi TAIL-RACE veloc should be such that the energy lost is less than 1%. This is difficult attain in low-head installations, but it should be considerably less than 1% with h heads. PENSTOCK (if any); with favorable conditions and short pipe line, the veloc may be $c_p = 0.1\sqrt{2gH}$, but with very high heads it is impossible to take ad vantage of this rule. It is fairly safe for heads between 35 and 180 ft, but for low lines the veloc must be reduced to save friction loss. In the distributing pipe near turbine the veloc may be increased to $0.13\sqrt{2gH}$, and in the inlet pipe, close to bine casing, to $0.17\sqrt{2gH}$, or $0.2\sqrt{2gH}$ for low specific speed and spiral-cased turbi but should be less than $0.1\sqrt{2gH}$ for barrel-cased turbines. DRAFT TUBE must be dimensioned that water enters it from wheel without change of veloc. It s be tapered outwards and downwards, as a diffuser for regaining part of the resi kinetic energy, and the outlet veloc should be slightly more than that in the tu (see above). It is inadvisable to use draft tube more than 1 ft in diam t length, otherwise the water column broken. TURBINE GATES. "Gate" part of the turbine which opens and cl to regulate entrance of water in acc with load. In Francis turbines Fig best makers use guide blades swi parallel axes. Each is coupled to moved concentrically about the tur by the governor, thus opening and cl the blades. This gives good effic at gate openings; the cyl gate, placed be guides and runner, gives poor effic load. GUIDE AND RUNNER VANES must enter guides and runners eddies or impact, change its veloc and continuously, move along smooth curves, and leave the tu the draft tube as nearly devoid of ene possible. Observing these rules, the veloc diagrams will be closed triangles Vane angles and sizes of channels must be designed so that the resulting velocities in Fig 33.

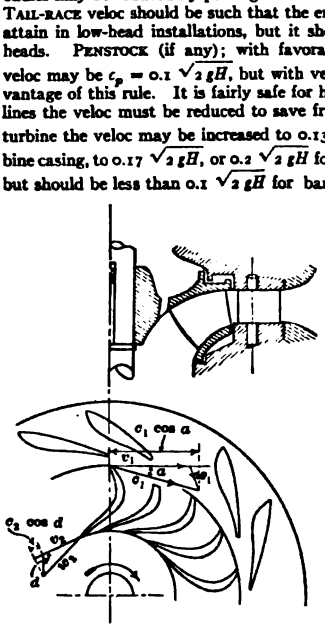

Fig 32. Guide and Runner Vanes (Francis Turbine)

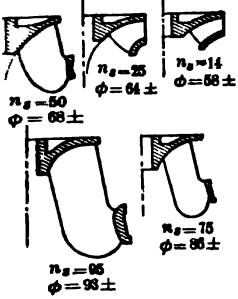
Turbine theory. The energy of the water on entering the turbine runner is $(W + g)\, c_1 \cos a \times v_1$ = available energy in a tangential direction at entrance (entrance diagram, Fig 32). Energy at discharge from the runner is $WH_2 = W(\cdots$ $\cos d \times v_2$ = available energy in a tangential direction at discharge (see discharge dia Fig 33). Hence, the work done is $W(H - H_2) = (W + g)(c_1 \cos a \times v_1 - c_2 \cos d \cdot$ WH_2 representing work lost. Other losses are due to impact at entrance to runner friction, water friction, water leakage, and eddies. These are considered collectiv percentage of the total available energy, and are subtracted from 100% to fi hydraulic effic. Then the above expression reads $gEH = v_1 c_1 \cos a - v_2 c_2 \cos d$. Substituting for $\cos a$ and $\cos d$ their values from the triangle relations for the entrance discharge diagrams (Fig 33),

$$EH = \frac{c_1^2 - c_2^2}{2g} + \frac{v_2^2 - w_1^2}{2g} - \frac{v_1^2 - v_2^2}{2g}.$$

Both forms of the fundamental equation are highly useful.

iciencies. Hydraulic effic of a turbine is the ratio of the energy delivered to r shaft to that of the water at the turbine entrance. It ranges from 80% to 95%, ding upon size and design of turbine. To get the commercial effic, from these s deduct 2 to 5%, for bearing friction and operation of the governor. The r the turbine the larger the mechanical loss. Thus, the over-all effic is 75 to Effic to be expected depends largely on the cost of the turbine. Reputable s guarantee over 80% over-all effic for stock turbines, higher guarantees being for special designs.

eds of Francis turbines. In considering the relation between output and speed, ntity called the SPECIFIC SPEED, n_s, is used, which is the speed at which a wheel run to develop 1 hp under 1 ft head. $n_s = n\sqrt{P} + H^{5/4} = n_x\sqrt{P_x}$, subscript x ng to 1 ft head conditions. n_x and P_x are found from $n_x = n + \sqrt{H}$ and $P_x = P +$



3. Types of Francis Runners

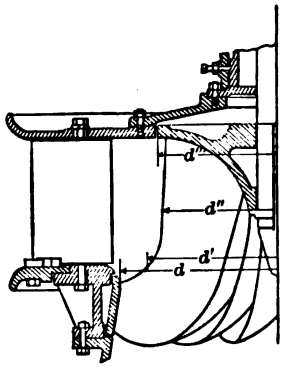


Fig 34. Modes of Measuring Runner Diam

esigning Francis turbines, n_s may be varied from 10 to 100; that is, a turbine can igned to develop 1 hp under a head of 1 ft, and by altering angles and dimensions ain any speed between 10 and 100 rev per min without loss of effic. Francis turbines e grouped according to unit speed into: Group 1, n_s = 10–25 (low reaction); 2, n_s = 25–50; Group 3, n_s = 50–78; Group 4, n_s = 78–100 (high reaction). 1 are for high heads, to about 600 ft. They are narrow axially and work nearly as e wheels. Group 4 are broad axially, are for low heads, and work with a high degree :tion. Fig 33 indicates the difference in design of these groups. This flexibility gn explains why the Francis turbine has superseded other types for reaction work.

ice of speed depends upon the nature of machinery to be driven. In the case generators, the speed must be regulated to suit the frequency. RUNAWAY SPEED. load suddenly ceases, the governor may not operate, and, when running at max the safety of the machinery being driven must be considered. Table 20 gives the ıy speed in percentage of the normal rev per min which may be expected for ıt makes of runner.

ct of head upon speed. From the formula for peripheral speed of a given tur- $r = (\pi\, dn) \div (60 \times 12) = \phi\sqrt{H}$, or $n = \left(1\,840\,\phi\sqrt{H}\right) \div d$. Thus, when ϕ) is constant, the rev per min vary with $\sqrt{H}$. But, commercial work requires a ıt speed; hence, as the head changes, ϕ must change from its best value. That is, ic for a given turbine is obtained at one head only.

meter of the runner is measured at the entrance edge. Fig 34, in con- ɔn with Table 20, gives the practice of different makers. "HAND" of the looking at the turbine from the shaft coupling, the runner is r' f it rotates clockwise; left-hand, if anti-clockwise.

te to Table 20. — *a* and column 8 are from (29), and *b* from paper No 1 138, Am Soc 1 Eng, by C. W. Larner. Value of ϕ, col 4, is for best effic as given in col 6. Col 5 tained by using the rev per min corresponding to ϕ at best effic, the hp at best reduced thus, $P \times (80 \div$ Best effic), and the actual head upon the turbine. Tur- are never guaranteed to give their best effic, but usually 3 to 8% lower, depending the setting, price, and keenness of competition. The foregoing shows that the table educed the value of n_s for the different turbines to an 80% guarantee basis, and the table is used the turbine selected has a slight margin of power. Where not wise specified, information in the table is from makers' literature, or received from by letter. Where incomplete, no information was obtainable.

ample: to show how turbine selection is made.
ven: $H = 16$; $P = 350$; $Q = 241$ cu ft per sec; current, 3 phase a c, 60 cycles.
rmal head, or difference between head water and tail water levels, is 16 ft. Then, al discharge being known from records, $P = [(241 \times 16) \div 8.8] \times 0.8 = 350$.
owing the rev per min desired (as 138.5 or 180), $n_s = n \div \sqrt{H} = 138.5 \div \sqrt{16} =$ or $n_s = 180 \div \sqrt{16} = 45$. Also, $P_s = P \div H^{3/4} = 350 \div 16^{3/4} = 5.46$; and $n_s = P_s = 34.6 \sqrt{5.46} = 80.7$, or $n_s = 45 \sqrt{5.46} = 105$.
ble 20, column 5, shows that makers number I, II, VII, VIII, X, and XI supply es which have values of n_s approximating 80.7. The I. P. Morris, Type O, is t, and other makers could meet the requirements by slightly modifying their de-

Diam of the Morris turbine is found thus: $\phi = nd \div 1\,840 \sqrt{H}$; whence, $= 138.5\, d \div 1\,840 \sqrt{16}$, and $d = 41.75$ in.
180 rev per min, the Leffel turbine is nearest. If the rev per min were not definitely d upon, the selection might be made thus: with the low head, the turbine would bly be a Francis high-reaction wheel, with $n_s = 78$–100. Then, using the same of H, P, and Q as above, and trying $n_s = 80$:

$$n_s = n \sqrt{P} \div H^{5/4} = n_s \sqrt{P_s}, \text{ and } P_s = P \div H^{3/2}.$$

tuting, $P_s = 350 \div 16 \sqrt{16} = 5.47$, and $n_s = 80 \div \sqrt{5.47} = 34.4$. Hence, $\sqrt{H} = 34.4 \times \sqrt{16} = 137.6$ rev per min. Also, $n_s = 138.5 \times \sqrt{350} \div 16^{5/4} = 80.7$. enerator for this speed would have $60 \times 60 \div 137.6 = 26.2$ pairs of poles (say es), corresponding to a speed of 138.5 rev per min, and a slightly different n_s. Other of n_s could be tried until a turbine was found which suited all conditions.

nmary of short expressions for turbine formulas:

$\sqrt{H} = n_s \div \sqrt{H_s}$;	that is,	n	varies with	$\sqrt{H}$,	when	ϕ	and	D	are	constant.
$D_s = n_s \div D$;	"	"	n	"	"	$1 \div D$,	"	ϕ	"	H	"	"
$\sqrt{H} = Q_s \div \sqrt{H_s}$;	"	"	Q	"	"	$\sqrt{H}$,	"	ϕ	"	D	"	"
$D^2 = Q_s \div D_s^2$;	"	"	Q	"	"	D^2,	"	ϕ	"	H	"	"
$H^{3/2} = P_s \div H_s^{3/2}$;	"	"	P	"	"	$H^{3/2}$,	"	ϕ	"	D	"	"
$D^2 = P_s \div D_s^2$;	"	"	P	"	"	D^2,	"	ϕ	"	H	"	"

$n_s = n \sqrt{P} \div H^{5/4} = n_s \sqrt{P_s}$, and $\phi = nD \div 1\,830 \sqrt{H}$

9. Impulse Wheels

ign is much simpler than that ction turbines. A jet of water the peripheral buckets tangen- to the wheel, with a velocity ponding to the head, less friction nozzle (Fig 35) (27, 28). Thus $\sqrt{2gH}$, where f is about 0.97. of runner = diam of pitch circle ; centers of buckets. Peripheral y is approx $v_1 = 0.45 \sqrt{2gH}$. ghr effic (80% or above), the D of jet or jets (in) must not diam d of the wheel (ft); if

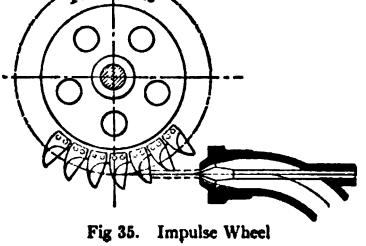

Fig 35. Impulse Wheel

5% lower effic be permitted, it may be up to $D = d + 9$. For high-pres turb with horiz shafts, it is possible (though undesirable) to use 2 or even 3 jets per wh For vertical-shaft wheels, 4 jets may be used. More than 2 wheels should not be f on one shaft. From what precedes,

$$Q = \frac{\pi D^2}{4 \times 144} \times c_1 = \frac{\pi D^2}{4 \times 144} \times 0.97 \sqrt{2gH}.$$

If $D = d + 12$, then $Q = \frac{\pi d^2}{4 \times 144 \times 144} \times 0.97 \times 8.02 \sqrt{H} = 0.000295\, d^2 \sqrt{H}$.

Example. Given: $H = 600$ ft; $P = 580$ hp; $Q = 10.6$ cu ft per sec.

$Q = 10.6 = 0.000295\, d^2 \sqrt{600}$; hence, $d = \sqrt{\frac{10.6}{0.000295 \sqrt{600}}} = 38.4$ in (say, 3 inches). Diam of jet $= 38.5 \div 12 = 3.21$ in. Since $n_1 = 0.45 \sqrt{2gH} = (r$ da (60 × 12), $n = 0.45 \frac{1840 \sqrt{H}}{d} = 525$ rev per min.

30. Automatic Governors for Turbines

This subject can not be dealt with here. For details of modern practice, and consid ations respecting effects of changes of load and pressure, see Bib 25, 27, 28, 29, 30.

31. Turbine Costs (31)

As nearly every installation is special, the price varies widely. Per lb wt of tu price may range from 8 to 30¢, depending upon the efficiency and regulation guara workmanship, metal used, style of setting, and whether or not a stock design is used specially designed turbine is required. Cost of the turbine itself generally varies tween 2 and 6% of total cost of the power plant. Cost of the turbine decreases w increase in head. Following figures are from (31):

Head, ft	Cost per hp	Cost of building per hp	Cost of a 16-in turbine		
			Head, ft	Hp	Cost per hp
60	$30–$7	$30–$4	30	52	$19 30
100– 600	12– 2	7– 2	60	158	6 75
500–2 000	8– 2	7– 2	100	318	3 14

Results of proposals for 4 turbines to give the same power under approx the same co ditions are as follows:

Hp	Rev per min	Head	Specific speed	Wt, lb	Total cost	Cost per lb, ¢	Effic guar	Design	Remarks
550	600	134	31.4	11 500	$1 750	15	None	Stock	26-in double discharge
500	514	138	24.3	....	4 000	....	"	Special	Governor included
550	600	142	28.8	33 000	6 000	18.2	Yes	Modified special	Guarantee
550	600	142	28.8	38 000	8 740	23.0	Yes	New design	Governor included

For other cost data, see Bib (29, 30, 31).

INTERNAL COMBUSTION ENGINES AND GAS PRODUCERS. (See also Sec 39, Art 5)

32. Classification and Characteristics

ommon basis of classification is the type of cycle employed, as the Otto or Diesel. cycle may be completed in either 2 or 4 strokes, resulting in a division into 2- e or 4-stroke cycle engines; abbreviated into 2-cycle and 4-cycle. Another classi- on is: gas engines and liquid-fuel engines, or gas, gasolene, and oil engines. The of governing, igniting the charge, and degree of compression (whether low, medium, gh) is a basis of classification; as is also the cylinder ar- ement (single or double-acting, single or multicylinder, or vertical).

ur-cycle engine indicator card for an Otto cycle is shown g 36. A new charge is drawn into the cyl on the first or on stroke AB, and compressed into the clearance space on econd or compression stroke BC, at or about the end of h ignition occurs and the charge instantly burns, causing press rise CC', at approx dead center. The high-press formed by combustion expand during the third or expan- stroke $C'D$, driving the piston before them; on this stroke is power delivered to the engine, enough being stored in the heel to run the engine until the next power stroke. On the exhaust stroke DA, burned gases are forced out. This type of engine has 2 valves, inlet and exhaust; latter is always mechanically operated, the former may be either mechanically oper- or automatic.

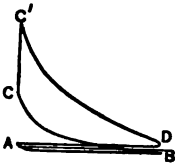

Fig 36. Otto 4-cycle Indicator Card

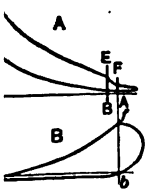
wo-cycle engine. A power stroke occurs once in each rev, the transfer of the charge out being made during a small part of the expansion and compression strokes. Fig 37 shows cards for this type of Otto engine, A being from the engine cyl, B from the compressor. At C ignition occurs, followed by expansion DE, as in the 4-cycle; at E the exhaust port is uncovered by the piston, causing the press to fall nearly to atmos. A little later, at F, the piston uncovers a second opening (transfer port); or an inlet valve is opened, allowing new mixture previously compressed to 6–10 lb above atmos press to flow into the cyl and drive out the remaining burnt gases. To facilitate this action, and prevent escape of new mixture through the exhaust, the 2 openings to the cyl are as far apart as possible and the piston end has a lip (Fig 38). The transfer port is closed at A (Fig 37), and the exhaust at B, permitting compression during the rest of the stroke. During compression in the engine cyl, suction bc occurs in the compressor cyl, followed by compression cf, while expansion takes place in the engine. In large engines a separate compressor or possibly 2 cyls, 1 for air and 1 for gas), are always provided, but in small es the charge is usually compressed in the crank case by the piston. This type of e is divided into 2-port or 3-port, depending on whether the inlet to the crank case ntrolled by a valve or by a third port, uncovered at the end of crank-case suction by ain piston. Card B, Fig 37, is from the 2-port engine in Fig 38, A. A 3-port engine wn in Fig 38, B.



37. Otto 2-cycle ndicator Cards

2-cycle engine having twice the cycles for the same rev per min gives greater hp e same size cyl, but not twice as great, since the m e p is less than for a 4-cycle, as o the effic. Chief advantages of the 2-cycle are: decreased piston area per hp and smaller wt and cost, decreased flywheel wt due to greater frequency of impulse, and ation of exhaust valves and gear (or, in small sizes, of all valves) hence further de- e in cost.

s and gasolene engines (32, 33, 34, 35). Gas engines may include engines run- on readily vaporized liquid fuels, as benzene, gasolene, and alcohol. To adapt a gas e to these fuels merely requires replacing the MIXING VALVE (which proportions the

quantities of air and gas) by a CARBURETER (see below). Hence, most engines listed as gas engines may be operated on gasolene and to some extent on alcohol. As alcohol permits higher compression, engines using it have somewhat smaller clearance spaces. The higher compression is not necessary, but tends to better economy. At present [illegible] the cost of alcohol in the U S prevents its competition with gasolene, but abroad it is largely used.

Oil engines use oils which can not be vaporized without adding heat. In general such fuels are injected into a projection of the cylinder termed the VAPORIZER, which, having no water jacket, is kept at a high enough temp for vaporizing the oil by the heat of the explosion. Prior to starting the engine the vaporizer is heated by an external source. There are 3 types of oil engine: (a) those injecting the fuel before the end of compression, all operating on Otto cycle and with relatively low compression, as the Hornsby-Akroyd and Mietz and Weiss; (b) those injecting fuel after a high compression and operating on Otto cycle, as the Franchetti; (c) those injecting fuel after compression and operating on Diesel cycle (Sec 39, Art 5). Types (b) and (c) are confined to large sizes and have about equal efficiency which is high due to high compression. They first compress air above the Diesel to press of 400–600 lb. the Franchetti to 200–300 lb. In the Diesel, oil is then injected at a rate required to keep the press constant by combustion, ignition taking place by the high temp of the air due to high compression. In the Franchetti, the proper amount of oil is suddenly blown into the cyl in a finely-atomized form, is ignited by a hot bulb in the cyl head, and burns with explosive rapidity. Both engines can produce 1 brake hp-hr on 0.5 lb of oil, or slightly less.

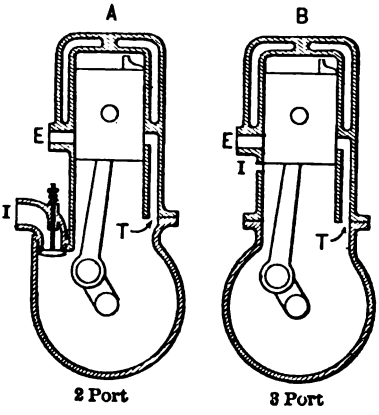


Fig 38. Two-cycle Engines, 2 and 3-port

33. Details of Operation (35, 37)

Governing. There are several modes; not only is the m e p changed, as in steam engines, but the number of cycles also. One of the commonest systems is the HIT AND MISS in which fuel is admitted only when speed is at or below normal, the engine running by the flywheel energy when speed is above normal. The mechanical means employed are numerous, the commonest being to arrange the push-rod operating the inlet-valve stem so that when speed rises it may be pulled to one side by the governor action, thus missing instead of hitting the valve stem. On engines having automatic inlet valves the exhaust may be held open, thus preventing creation of a sufficient vacuum in the cyl to open the inlet, or the inlet may be mechanically held shut. This economical form of governing is confined chiefly to small, cheap engines, where close regulation is not essential. Governing by throttling is usual on large engines; a butterfly valve or other restriction in the mixture pipe is operated by the governor, or the latter varies the lift of the inlet valve. Also, the time of closure of the inlet valve may be altered, giving a cutoff effect. See QUANTITY GOVERNING. Changing the amount of fuel per cycle, or QUALITY GOVERNING, is usual for oil engines, the quantity being varied by changing the length of the pump stroke, or by-passing some of the oil pumped.

Ignition. At present (1916) the hot-tube and flame ignition systems have been superseded by electrical means, except in oil engines where the hot bulb used for vaporizing the fuel also serves for ignition, and, in the Diesel engine, where the temp due to compression is high enough to make separate ignition devices unnecessary. Electric systems comprise the

H-SPARK and the MAKE-AND-BREAK. In the former, the secondary circuit of an in-ion coil is led into the cyl through the insulated terminal of a spark plug. At the er moment the primary circuit of the coil is closed and a spark (or series of sparks in better forms) jumps a short gap in the secondary circuit at the end of the plug. Make-break system has a single low-tension circuit; just prior to the moment of ignition the uit is closed, and then suddenly broken within the cyl at the proper instant, causing ark at the point of breaking. To increase the spark intensity, an inductance coil is ully placed in the circuit. Breaking the circuit may be done mechanically, or in the er forms electrically; the latter is preferable in requiring no moving element to pass ugh the cyl wall. Any source of current, as primary or storage batteries, magnetos, ther generators, may be used for ignition. Frequently, for greater reliability, there 2 sets of ignition apparatus, supplied from different sources.

tarting devices. Large engines are started by admitting compressed air to one or e cyl at the proper time, until a mixture has been drawn into and fired in one of them, reupon the air is shut off. Small engines are started by turning them over by hand l an explosion occurs, or by electric motors. Automobile engines nearly always have tric starting motors, which become generators and supply current for ignition, stor-battery, and lighting, when the engine is in operation.

ooling is accomplished by water jacketing the cyl, except in very small sizes where, dding ribs on the cyl, enough radiating surface is obtained for cooling. In larger s, the exhaust valves, and in double-acting engines, the pistons and rods, are also er-cooled. Cooling water must be clean and not deposit much salt on heating; dirty ard water fills the jackets with mud or scale, causing overheating. Water may be ved to go to waste, or artificially cooled (Art 15). From 3 to 5 gal per hr per hp are cient, if a reasonably cool source is available.

arbureters prepare explosive mixtures from the lighter liquid fuels, as gasolene or hol. Strictly speaking, the term carbureter is limited to apparatus where no external is applied, those requiring heating being called vaporizers (Art 32). But, with the of heavier and heavier grades of fuel, many so-called carbureters are now equipped i means for applying heat, as from the engine-jacket water or exhaust. Carbureters ortion the fuel and air, vaporizing the fuel to some extent and mixing the two. This ne by allowing the fuel to flow from a reservoir, in which the level is kept constant, the air-inlet pipe. As the press in this pipe drops with increase of air flow, more fuel flow. If air and fuel followed the same law of flow with press drop, a carbureter sted for any condition of load or speed would be correct for all conditions. But, the of fuel increases faster than that of air, tending to cause too rich a mixture at heavy s or high speeds. The numerous carbureters on the market differ chiefly in the mode rrecting this defect; most of them use a manual or automatic device, or a combina-of these, for introducing extra air when the conditions normally cause a rich mixture. fuel reservoir is called the float chamber, when the liquid level in it is regulated by a . This device is limited to engines in which the supply is under a gravity or press l. For stationary engines insurance regulations usually forbid its use, in which case mp forces fuel to the reservoir in excess of the engine demand, the surplus returning he tank. The fuel flows from the reservoir through a spray nozzle, controlled by a le valve.

r light fuels the heat in the atmosphere usually suffices for vaporization; for heavier ls, heat is applied by drawing the air partially or wholly from a jacket on the exhaust , or by allowing the engine-jacket water to pass through a jacket on the carbureter. essive heating is bad, as the engine power is proportional to the density of the charge. mplete vaporization, especially in multicyl engines, is apt to cause a non-homogeneous ture. For mixing action, carbureters depend chiefly on the throttle and valve ob-ction, and on bends in the supply pipe (37).

34. Power, Efficiency, and Cost

xpressions for calculating power, thermal effic, and fuel consumption of internal bustion engines are given in Sec 39, Art 5, and Tables 21, 22 show values of com-sion ratio, diagram factor, and effic, for different sizes of engine and kinds of fuel. ir brake hp is the product of i h p and mech effic, values for which are in Table 23.

avoid the common error of purchasing gas engines of too low a power for their work. Brake hp of automobile engines is found by the empiric formula, brake hp = $D^2N \div 2.5$, where D = diam of cyl, in, and N = number of cyls.

Tables 26 to 30 give commercial sizes of different types of internal-combustion engines.

st of internal-combustion engines varies greatly, due to competition and other s. The writer has had 2 bids by different makers for the same contract, one 40% r than the other. Kent quotes following expressions by Wickenden, as applying gines suitable for electrical work: Cost in dollars for 50–125 hp = 400 + (40 × 125–250 hp = 2 500 + (20 × hp); above 250 hp = 32 × hp. A similar expression is engines in general from 10–300 hp is (33.6 × hp) − 115. For gasolene engines, ring expressions by Prof A. A. Potter represent the aver of a large number of cases: 75 hp, throttle-governed, cost (dollars) = 310 + (36 × hp); up to 100 hp, hit-and-governed, 141 + (25 × hp). For a number of gasolene-operated irrigation plants, 8–30 hp, price per hp was about $100. For oil engines, up to 400 hp, cost is 400 + hp). Diesel 4-cycle, up to 600 hp, $60 per hp; 2-cycle, 750–1 500 hp, $42 per hp. st per hp, Franchetti engines: 100 hp, $61; 140 hp, $64; 180 hp, $68; 200 hp, $60; p, $61. Hornsby-Akroyd: 20 hp, $58; 35 hp, $46.

35. Gas Producers and Auxiliaries (33, 38, 41, 42)

nstruction. A gas producer consists of a metal shell, usually cylindrical, lined with rick and having provision for supporting the fuel bed and blasting it with air or a ure of air and steam. Fuel bed is 4 ft or more thick, comprising a zone of ash at ottom, next a high temp zone of burning fuel and finally a layer of fresh coal. The nay be supported on a grate, fixed or revolving; or on a concrete pier rising from a of water, into which the sides of the producer extend, thus forming a water seal igh which the ashes are raked out. Fuel is charged from time to time through a hopper that of a blast furnace, to prevent an outrush of gas or inrush of air.

peration. The process consists in roasting off volatile matter of the fuel, and then izing the carbon to CO or CO_2 by the O in the air and steam; H of the steam is set and the ratio of CO to CO_2 depends on temp and thickness of the bed. Steam is to reduce the temp, the exothermic reaction of the oxidation of the carbon being ly neutralized by the endothermic reaction of breaking down the steam. Without e temp is usually high enough to fuse the ash, forming clinker and preventing flow of hrough the bed.

uels. Though any fuel rich in carbon may be used, those containing much volatile ter are disadvantageous due to variation in gas quality and difficulty in removing and soot formed by reduction of the heavier hydrocarbons. Coking coal is unsatis-ory, as it cakes and tends to block the flow of gas like clinker. Some producers have hanical pokers to break up the cake. The following fuels are used in producers: racite or bituminous coal (non-caking), coke, lignite, charcoal, oil, wood, peat, and te products.

last may be forced through the bed by building up pressure before the bed is reached, n PRESSURE PRODUCERS, or by creating a deficiency of press beyond the bed, as in TION PRODUCERS. In pressure producers (commoner in the larger sizes), the blast aused by a steam jet or positive blower (usually the former, as steam is required in blast and the blower serves as a good mixing device). In the suction type, the ine piston draws the blast through the producer (a small auxiliary blower being used starting up). Though this type requires no gas holder, it is found disadvantageous employ the engine for producing blast, and a rotary blower or fan is generally used draw the gas from the producer and deliver it to the engine. The suction producer imited to the better grades of fuel, as anthracite and coke, but is safer, because, as ts are inward only, the burning of some of the gas in the producer is all that ca- --

sult; whereas any leak in a pressure producer allows escape of very poisonous gas and may result in forming an explosive mixture in the room or building.

The draft may pass upward through the bed, UP-DRAFT PRODUCER; downward, DOWN-DRAFT PRODUCER; or both ways, COMBINED-DRAFT PRODUCER. In the two latter the volatile matter passes through the combustion zone and is either reduced to simpler forms or is completely burned.

Producer auxiliaries. The term PRODUCER SET covers producer, auxiliaries, and engine. The most important adjunct is the cleaning and purifying device, usually comprising a scrubber and filter or tar extractor. The SCRUBBER is a chamber filled with coke or similar material, through which the gas rises while water passes down; sometimes it is a simple pipe, up which the gas travels, passing water sprays at short intervals. FILTERS, of saw dust, excelsior, or mineral wool, extract tar and other liquids, but are only partially successful. TAR EXTRACTORS, other than filters, are centrifugal fans or beaters for churning the gas and water, causing the tar particles to collect in large drops which then float away. A recent filter seems to depend on static electrical action causing minute particles of tar to coalesce into drops large enough to fall by gravity in an ordinary separator; tar so recovered is water-free, and has value as a by-product. Suction producers must also have apparatus to supply steam for humidifying the air. As no press is required, the steam may be made in the producer jackets, or in a boiler or evaporator heated by the gas on its way to the scrubber. The proportions of steam and air must be controlled; best done by using saturated air, but of different temp. For a pressure producer a separately fired boiler generates steam for the blower.

Mond producers recover ammonia from the coal. An excess of steam is supplied to the producer, reducing the temp of the reaction and hence increasing the CO_2 content but preventing the breaking down of the ammonia. After purification the gas passes to a scrubber supplied with dilute H_2SO_4 instead of water, which absorbs the ammonia as sulphate, and upon evaporation the solid sulphate is obtained.

Rating of producers is more uncertain and difficult than that of boilers; the term horsepower of a producer is incorrect, as no mechanical work is done. However, a producer is usually designated as being of a certain hp, meaning that it will supply gas for an engine of that hp. On the basis of 1 to 1.5 lb coal per hr per engine hp, and a rate of combustion of 7 to 10 lb per sq ft of producer grate surface (figures realized in average use of both types), a producer will supply about 7 hp per sq ft of grate.

Table 31. Producer Dimensions (Smith)

Hp rating	Coal per hr, lb	Space required, ft			Hp rating	Coal per hr, lb	Space required, ft		
		Length	Width	Height			Length	Width	Height
50	65	12	7	20	175	220	15.5	9.5	22
75	95	12.5	7.5	20	200	250	16	10	22
100	125	13	8	20*	250	315	17	11	22
125	160	13.5	8.5	20	300	375	18	12	22
150	190	14	9	22	....	.....	.....	.....	.....

Producer costs. The following figures are from actual installations:

Suction producers, up to 300 hp,	$252 + (14 \times hp)$	Prof A. A. Potter
Pressure " " " 300 "	$860 + (15 \times hp)$	
Suction " and auxiliaries, 0–200 hp,	$570 + (46 \times hp)$	
Suction producers and auxiliaries,	$150 + (11 \times hp)$	Prof W. S. Wicksenden (kent)
Pressure " " " to 200 hp,	$1\,000 + (16 \times hp)$	
" " " " over 200 hp,	$2\,000 + (15 \times hp)$	

Producer performance. For information, see Bib 5, 33, 38, 41.

APPARATUS FOR TESTING POWER PLANT

(Codes governing the testing of power-plant machinery are published by Amer Soc Mech Engs and may be purchased from the society's Secretary, 29 W 39th St, N Y. See also Bib 13, 14, 15, 16. Following suggestions, relating to methods and procedure may be of assistance in laying out and running tests.)

36. Preparations. Pressure and Temperature Measurements

Preparations. Define the object of the test, and decide upon the limit percentage of allowable in the results. Determine the quantities to be measured, by analysing xpressions denoting the final results (which are generally compound units) into ities of a single dimension, since there are very few methods or instruments for uring quantities of more than one dimension. Thus, the determination of water alls for the wt of dry steam per hr per ihp, and the measurements necessary are: steam used, dryness factor, length of run, m e p in the cyl, length of stroke, area of ., and number of strokes per min.

Choice of instruments and methods of measurement for any particular investigation ds upon the methods available and the limit percentage of error allowable. If an ate error of 20% is permissible, it is unnecessary to use apparatus of extreme acy; but, if the results will be worthless unless accurate within a very few per cent, eless to proceed unless accurate methods are available.

After deciding upon the test methods, a DIAGRAMMATIC SKETCH should be made of the ne to be tested, with all instruments and measuring apparatus shown in their proper re positions. This sketch serves as a guide in setting up the apparatus. A log of the necessary readings is then drawn up, with a column for each variable and for each constant. The log should also contain spaces for description of apparatus , date of test, names of observers, and remarks concerning unusual occurrences the test. The completeness of the log and sketch of instrument arrangement l be proved by seeing that there is a place for every instrument reading, and that the las to be used for calculating final results can be fully satisfied for the log readings.

Pressure measurements. The ordinary press units are: lb per sq in, inches of mercury, of water, and ft of water. 1 lb per sq in = 2.0359 in mercury at 32° F = 27.71 in 69 ft water at 62°. Lb per sq in is used for all ranges of press, except vacuum and up to 10 or 15 lb above atmos, which are generally expressed in inches of mercury. ce draft, press in ventilating ducts, and other small pressures, are expressed in inches ter. For hydraulic work, ft of water are used almost exclusively.

Pressure gages of the Bourdon tube type, with scales ranging from 30 in vacuum (15 lb to several thousand lb, are of either the indicating or recording form. Diaphragm are not widely used. Gages should be CALIBRATED before and after use. The reliable gage tester is the "dead-weight" tester. Measurements by mercury meter, of either the U-tube or cistern form, are standard if the mercury be pure. ty of mercury is altered by dissolving tin in it; evidence of such adulteration is by subjecting a mercury column and water column to the same press, and com- the ratio found with that for the pure liquids. Pure water should be used in manometers, but the ordinary impurities in fresh water will not materially affect gs. For measuring very small press at temp below 32°, other liquids may be used nometers. Such readings should be transposed into inches of water, by direct com- n with a water manometer, or by measuring the sp gr of the liquid by a hydrometer. mall press may be measured by a water manometer with tube inclined at a consider- ngle to the perpendicular, thus causing large longitudinal travel of the surface of uid for small change in elevation.

Temperature measurements are made by the Fah scale by engineers, though chemists e Cent scale. 1° F = 5/9° C. Temp in °F = temp in °C × 9/5 + 32. (For con- n table, see Sec 37.) The mercury thermometer, generally used for measur- np, is made with a range of scale from −40° to 1 000° F. Indicating and recording ments are also made, in which the actuating portion is a bulb filled with liquid , connected by a flexible tube to a Bourdon tube which moves the pointer or record- n. Electric pyrometers, indicating or recording, are of either the thermo-couple stance type, for all ranges of temp to 3 000° F. Optical and radiation PYROMETERS measuring temp from 1 000° F up. High temp is sometimes gaged by the fusing erials which have well-defined melting points.

Temperature measurement of gases is difficult. The temp of a gas flowing through may vary considerably in different parts of the cross section, and the true aver is o determine. Also, the instrument must not be exposed to radiation from some at a temp higher than that of the gas. Failure to shield the instrument from su- ion may cause errors of several hundred deg. As gases are transparent they n

not radiate heat, and, if optical or radiation pyrometers are used for measuring ... temp, a solid object must be placed in the gases at the point where the temp is ... measured and upon which the instrument is sighted. Such an object should be dull colored; all optical or radiation pyrometers are calibrated for a black object.

37. Measurement of Weight, Dimensions, Speed, and Power

Measurement of weight is made by either lever or spring balance. Spring balances are often more convenient, but their length of scale is limited and their percentage error relatively high. After long use their accuracy is more questionable than that of lever balances. Wt may be determined indirectly by measurement of the volume of an object when its sp gr is known (Sec 1, Art 3).

Measurement of length, area, and volume. Small irregular areas on drawings may be measured directly by a planimeter. Irregular volumes may be determined by weighing in air and immersed in water, the difference being the wt of water displaced, from which volume is computed. Differences in altitude may be determined by measuring the difference in press in a water pipe running from one point to the other. The water must not be flowing when the measurement is made.

Measurement of speed. Many types of stroke or revolution counters are used. Some are attached to the machine; others are for hand use. They are the most reliable for general service, especially when the speed varies. TACHOMETERS indicate or record directly rev per min. They operate by the centrifugal force of solids or liquids, voltage of an electric generator, or synchronous vibration. They should be carefully calibrated before use in important work, and it is wise to check their readings by a revolution counter. They are unsatisfactory for variable speeds, because averages must be estimated. Chronographs make a graphical record of each revolution, with simultaneous time record.

Power measurements. Standard unit in the U S is the horsepower = 33 000 ft-lb per min = 0.7457 kilowatts. Power developed in cyls of engines, pumps, or compressors is indicated horsepower (ihp). It is measured by an engine INDICATOR, a special form of pressure gage which records on a piece of paper wrapped on a drum, caused to follow the motion of the piston. In nearly all indicators the press-recording mechanism is driven by a spring-opposed piston, the cyl of which is connected with the engine cyl. Springs are furnished of a wide range of strength, and the scale marked on the spring indicates that the recording pencil will rise 1 in for that unit press. Mean effective press (m e p) is the aver height of the recorded diagram, inches, multiplied by the scale of spring used. The indicator drum, usually 1.5–2 in diam, is generally driven from the engine crosshead, with the necessary reducing motion. The indicator is connected to the cyl through a special cock, which has a standard 0.5-in pipe thread on one end, the other end being special for each make of indicator. Each indicator must have its own cock. Indicators are often used for recording rapidly fluctuating press in pipes, the drum being designed so that a continuous roll of paper is passed over it.

Power output of machines may be measured by absorption or transmission dynamometers. The absorption dynamometer or PRONY BRAKE is easily made in any shop, the details of its design being governed by the work to be done. Fig 39 shows a Prony brake made of wood blocks held together by steel bands. The arms are of pipe or iron. Friction is adjusted by handwheel. Bhp = $2\pi LN \times$ rev per min $\times W \div 33\,000$, where W = net wt registered on the scale, less unbalanced wt of the brake and support, and L = length of brake arm, ft. Prony brakes are rarely used to absorb more than 200 hp, the limitation lying in the difficulty in removing the heat generated. This difficulty may be overcome by water-cooling the brake. This is done by using a brake pulley with an internally-flanged rim, which when running will hold a body of water in contact with the pulley rim. Another absorption dynamometer is the Alden brake, made with a rotating steel disk surrounded by

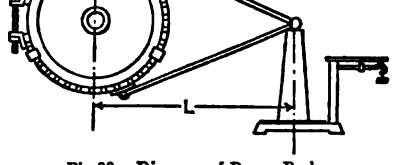

Fig 39. Diagram of Prony Brake

g. Within the casing are copper plates, pressed against the disk by water press. r is determined by measuring the torque of the casing, the heat generated being d off by the water.

umber of HYDRAULIC BRAKES are made on the principle of a centrifugal pump, with s on casing as well as on rotor. Power is absorbed by the eddy-current friction, and asured by the torque of the casing. These brakes have been made to absorb over hp. At low speeds their capacity is relatively low, but increases about as the cube e speed.

electric generator may be used for measuring the power of a machine, if its effic is n. ELECTRIC BRAKES are made on this principle, with the generator stator hung ll bearings, so that the torque can be measured as for any type of brake. By run- them as motors they will also accurately measure power input to a machine.

8. Measurement of Water and Flow of Steam. Calorimeters

asurement of water or other liquids. The most accurate mode of weighing liquids anks on scales. When measured volumetrically, by change of level in a calibrated the area of the water surface should be as small as possible at the points where the urements of depth are taken, so that a small error in depth will not make a large in volume. Flowing water is measured by weirs, Venturi meters, pitot tubes, s, and nozzles (Sec 38). Piston and disk meters, also used for small and intermittent should always be set up so that they can be easily calibrated. Disk meters as usu- onstructed will not handle hot water.

asurement of steam flow should be made in the form of water, either before it is the boiler or after it leaves a condenser. STEAM METERS operate on the pitot tube, ri meter, orifice, or float principle. Chief source of error is in the recording or in- ig device, which, for accuracy, should correct for press and moisture content or eat. A steam meter may be calibrated by placing it in a steam line from a boiler, d water being weighed, or in the line to an engine exhausting to a surface condenser.

asurement of gas flow is more difficult than that of steam, as the meters are not ly calibrated. Small quantities of gas can be measured in gasometers or gas holders, et or dry gas meters give fair accuracy for small flow. But, large quantities of ist be measured by a RATE-FLOW METER. Pitot tubes, Venturi meters, orifices of s forms, and anemometers, are generally used. The standard meter for measur- is the Thomas electric gas meter, in which the gas is heated by an electric resistance d the amount of current measured. The wt of gas flowing can then be computed he rise in gas temp and the specific heat of the gas. The apparatus is expensive, generally used for calibrating the simpler and less costly forms of meters.

um calorimeters. For most work a throttling calorimeter is best. It consists of a ghly lagged metal chamber (often made of pipe fittings), with a thermometer cup top and an opening to the atmos at the bottom. It is connected close to the steam d the steam flows into it through a small orifice. Total heat in the steam is com- from the amount of superheat indicated by the calorimeter thermometer. As nciple of operation depends upon the difference in total heat, the range of this ient is limited, about 4% moisture being the max at 100 lb steam press and 5.5% lb press. For very wet steam a separating, or combination separating and throt- lorimeter should be used. The chief source of error in steam calorimetry lies in the y of obtaining a truly representative sample of steam; hence care should be taken ing the sampling nipple.

calorimeters are of 2 classes, those which operate continuously and those operat- single charges. Continuous calorimeter is used for gas and light fuel oils. The n form resembles a small fire-tube boiler, set vertically, with an internal fire box. el burner is placed within the fire box, the air for combustion being drawn in at tom. Water is circulated around the tubes, and the heating surface is sufficient the gases of combustion to be cooled down to atmos temp. The relative quan- water and fuel are so adjusted that the rise of water temp is from 20 to 30° F. u per lb or cu ft of fuel can be computed from measurements of the amount of ned, wt of water heated, and the use in water temp. The discontinuous type of eter, generally known as the bomb calorimeter, is for solid fuels and heavy oils. ed amount of fuel is placed in a heavy chamber or bomb, together with oxy-

gas under press, or a chemical containing oxygen to support combustion. The bomb placed in a fixed wt of water, in an insulated chamber, and the charge is fired by an electric spark. The rise of water temp measures the heat units set free.

39. Contracts and Acceptance Tests

When contracts for power machinery contain a clause guaranteeing the performance the wording of the guarantee should be such that its meaning can not be mistaken, and that the operating conditions are clearly specified under which the performance test is made. Unless otherwise agreed upon, the acceptance test is run by the engineer of the purchaser. The contractor is allowed to have a representative present, who shall have access to all readings, though without right to interfere in the running of the test, that he may see that the machine is properly adjusted before the test is begun, and in the case of boiler tests he is generally permitted to direct the firing, but not to furnish the fuel. The engineer in charge is responsible for maintaining the operating conditions for which the guarantee is made. When there may be difficulty in maintaining such conditions some agreement should be reached by the contracting parties as to allowances to be made in fulfillment of the guarantee on account of such variations of conditions. When it is necessary to make measurements by other than generally accepted methods, a mutual agreement on the matter should be reached before the test begins. All readings should be entered upon the official log sheet (Art 36), which should be retained in its original form because, in case a lawsuit develops upon the results of the test, that sheet alone has legal standing in court as evidence.

1. Gearing

Characteristics. The term as here used means tooth gearing; friction gears and other special forms will not be considered. According to the shape of the teeth gears are divided into involute and epicycloidal; former has many advantages and the latter is little used. PITCH CIRCLE (Fig 1) is the base to which gear calculations are referred. The pitch circle diameters of 2 intermeshing gears are equal to the diameters of 2 equivalent cylinders, rolling in contact without slipping. CIRCULAR PITCH is the distance measured on pitch circle from center to center of teeth: hence

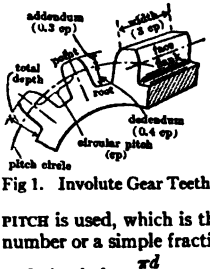

Fig 1. Involute Gear Teeth

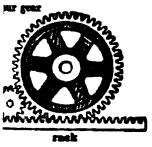
$$\text{cir pitch} = \frac{\text{pitch circumference}}{\text{no of teeth}} = \frac{\pi d}{N}, \text{ where } d = \text{diam}$$

of pitch circle and N = number of teeth in the gear. Circular pitch is not convenient for determining number of teeth or pitch diam; hence, the DIAMETRAL PITCH is used, which is the number of teeth per in of diam, and is either a whole number or a simple fraction. Then, no of teeth = pitch diam × diametral pitch, and cir pitch $= \frac{\pi d}{N} = \frac{\pi d}{d \times \text{diametral pitch}} = \frac{\pi}{\text{diametral pitch}}$. In this way proportions are readily calculated. Thus, for a 2 diametral pitch, if the wheel has 20 teeth the pitch diam is 10 in; or, if a wheel has 60 teeth and the pitch diam is 20 in, the diametral pitch is 3, and the circular pitch is

ar gears are gears in one plane, with their axes parallel. If the radius of pitch circle nite, the circle becomes a straight line, resulting in the RACK. Spur gears having ame pitch are interchangeable (Fig 2). HERRINGBONE GEARS are used when end t on shafting is to be avoided. Their teeth are cut at an angle with the axis (Fig 3).



Spur Gears and Rack

Fig 3. Herringbone Gears

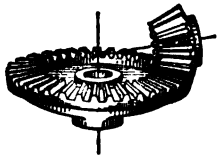


Fig 4. Bevel Gears

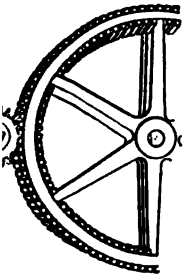
rel gears are those of which the axes are in one plane and intersect; they are called gears if both are of the same diam. Bevel gears are not interchangeable for the pitch, but must be made in pairs (Fig 4).

rm and worm-wheel are gears with axes at right angles n parallel planes (Fig 5). They must be made in sets.

Fig 5. Worm and Worm-wheel

nstruction. Metal gears are usually of C I or steel; brass, metal, raw-hide, paper, and cloth, are used for special Teeth cut in the solid rim give the most perfect form oth, and are known as CUT GEARS. If cast in a sand l the tooth outline is less accurate than the cut gear; ration they are noisy, noise increasing with speed. Small are cast in steel moulds under pressure, known as die-g. They are accurate in form, but can be made only of metal and commercially must be duplicated in large quan- because of the expensive dies. Gearing is also made of serted tooth type. The teeth, of maple wood, are inserted -I rim; one wheel of a pair has wooden teeth, the other, ary metal teeth (Fig 6). Advantages: they run quietly and in case of accident the n teeth, which are the ones to be damaged, are readily replaced. Wooden teeth are made in coarse pitches only. They are wider on pitch circle than the iron tooth, in the proportion of 0.6 circular pitch for the wooden to 0.4 circular pitch for the iron, making strength and wear more uniform. Gears of large sizes are made in halves or sections, bolted together, and can therefore be placed anywhere on a shaft.



). Wooden-tooth Gear

Spur-gear ratios for single reduction of speed seldom exceed 6 : 1; in some special cases as high as 10 : 1. When greater reduction is required, gear trains may be used; in that shown in Fig 7 the driver has 20 teeth and meshes with

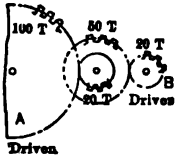


Fig 7. Compound Gear Train

tooth wheel, giving a 2.5 : 1 reduction; attached to the same shaft as the oth wheel is a 20-tooth wheel, forming a COMPOUND GEAR. The latter l meshes with a 100-tooth wheel, giving a 5 : 1 reduction, or a total of 5 = 12.5 : 1.

andy rule for calculating gear ratios in compound trains is $\frac{\text{Product of the drivers}}{\text{Product of the driven}} =$ ratio; in which diameters, numbers of teeth, or rev per min may be used. Where reductions of 3 or 4 : 1 are made, the teeth on small gears wear much faster than

those on the large. To equalize wear, the smaller or pinion gear is made of harder ma as steel, while the larger is of C I. When the number of teeth are exact multiples tooth on the pinion will always mesh with the same tooth on the large wheel, and case there were opposed hard and soft spots in the teeth, wear would be rapid. In where exact gear ratios are unnecessary, as for triplex pumps, the larger gear has an ex tooth called a HUNTING TOOTH; thus, if the pinion has 20 teeth and the large wheel teeth, every tooth on the pinion will come in contact with every tooth on the la gear, thus distributing the wear more evenly over both wheels.

Strength of gear teeth. The weakest part of a tooth is at the root in the sm wheel, as at *a*, Fig 8, and in practice, the root of the tooth is bounded by the ra lines, as shown. Upon this basis have been calculated the formulas for the streng teeth, the smallest number of teeth being 12. As the number of te increases, the root width *a* and the strength also increase. Wid face for good contact is generally assumed to be 3 times the circ pitch, but this is sometimes exceeded. Spur and bevel gears are tainable of almost any size, catalogues giving stock sizes in pi from 0.5 to 46 diametral pitch. Selection of proper pitch de upon size of gear and power transmitted; in general, the larger gear the greater the power transmitted and the coarser the pi

Fig 8.

WORM-GEAR REDUCTIONS are much higher than for other types of ing. If the worm is a single thread, for each revolution of the w the worm-wheel will move 1 tooth; for a double, triple or quadruple thread, the wh will advance 2, 3, or 4 teeth. In practice, the wheel should have not less than 2 and as the diams of worm and worm wheel have no influence on the gear ratio, the cor proportions must be carefully worked out to secure efficient operation. In ma catalogues, ratios of 15 : 1 for quadruple threads, or 129 : 1 for single thread, are quot In all gearing, positive ratios are obtained; there is no slipping as with belting.

2. Belting

Principles of pulley and belt transmission. Since slippage always oc exact speed ratios can not be obtained. Resistance to slippage depends o the coeff of friction, area of surface in contact, and the press on pulley fac the belt pull. The effective pull is equal to the difference between the tens on the tight and slack sides of the belt. The angle over which contact ta part is the angle of wrap. Coeff of friction depends upon the materials surfaces and the condition of the two surfaces. For ordinary iron or wooden pulleys and leather belting, the coeff is 0.3 to 0.4 aver for dry surfaces, and say 0.15 to 0.2 for wet or greasy surfaces.

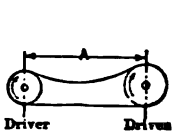

Fig 9. Favorable Belt Drive

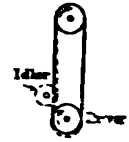

Fig 10. Unfavorable Belt Drive

For most operation the coeff must be as high as possible. It is evident that the best drive is that shown in Fig 9, that is, the tight side below, since any stretch in the belt increases the angle of wrap, one of the power factors. The worst drive is shown in Fig 10. The lower pulley being the driver, any stretch in the belt causes excessive wear. In practice this form of drive requires an idler pulley and lower tension.

Power transmitted by a belt depends first upon the difference in ten between tight and slack sides, and second upon the belt speed. With surf a 200 coefficient, and 180° angle of wrap, the ratio of tension on tight side (T_t) to tension on slack side (T_s) averages about 2.5, that is, $T_t \div T_s = 2.5$. This ratio varies from 2 in small sizes to 3 in large, the pulley diams being equa practically so. To solve this formula either T_t or T_s must be known. T_t is obtai by dividing the breaking strength of a piece of belting, from which is determin

ife **working stress.** Since belting varies in thickness, the tension per in lth is generally given, rather than tension per sq in of cross sec.

t **speed.** Increase in speed, other conditions unchanged, increases power delivered, a certain limit. But, as the belt travels over the pulley, centrifugal force throws it from the pulley face and partly neutralizes the driving force. The limit is reached peed of about 5 000 ft per min; any further increase of speed decreases the power nitted. Hp = [pull of belt (lb) × veloc (ft per min)] ÷ 33 000. In practice, to 4 500 ft per min are aver speeds. Velocity must sometimes be sacrificed, due to ge diam of pulleys required for given rev per min of shafting, and the belt width is ed to transmit the required hp. Belting is usually of leather, or several plies of covered with rubber and pressed together. Woven belts, or thin steel bands, so used.

ather belts are of single, double, or triple thickness. Makers' catalogues ables of the hp transmitted by different kinds of belting at given speeds, gures being based upon an arc of contact of 180°, and an aver working ten- per in of width found satisfactory in practice, viz: 40 lb for single, 70 lb ouble, and 100 lb for triple thickness. Thus, if a belt running at 3 000 ft in is required to deliver 60 hp, the total pull would be $P = 33\,000 \times 60 \div$ = 660 lb. For a double belt a pull of 70 lb per in of width is allowable, g 660 ÷ 70 = 9.5, or say a 10-in belt. It is good practice to design a belt capable of transmitting 25% excess power for small sizes and 5% excess arge drives. One maker recommends the following rule, which includes ve power: for single-thickness leather belt, the hp per in of width = belt l in ft per min ÷ 800; for double thickness, divide the speed by 500.

ting should be properly cleaned and dressed with a reliable compound to keep it nd pliable, and be systematically inspected. Belts exposed to dampness or acid require special treatment in manufacture. If a belt is stretched to its limit to mit a given hp, its life is short. Since tension produces a heavy pull on shafting earings, causing friction and wear, it should be a minimum for the work to be done. tension gives long life and increased first cost; high tension, a short life and lower ost, but with more stoppages for belt repairs. Shafts can be driven at almost any , if provided with idler or guide pulleys. If the distance between centers of shafts iple (Fig 9), the weight of belt on slack side produces the necessary tension, and h increases the angle of contact, which is also favorable. If distance between centers rt, the belt must be stretched to produce necessary tension. Slippage, which will after a short time, due to increased stretch, can be overcome by adjustable idler ys placed on the slack side, close to the driving pulley, so as to increase the arc of act (Fig 10). If the distance between centers is excessive, the tight side will sag, easing the angle of contact, and the belt is liable to flap, ng the faces to rub on each other. To get proper tension putting on new belting some makers recommend cutting in of belt for every 10 ft of tape line measurement. For ing shafts in opposite directions, crossed belts (Fig 11) sed, but should be avoided if possible, because the belt rubs at point of crossing. other types of belt drive, the makers should be consulted. Leather belting can be from 0.5 in to 72 in wide; widths from 0.5 to 1 in vary by ⅛ in, from 1 to 4 in by in, 4 to 7 in by 0.5 in, 7 to 26 in by 1 in, 26 to 40 in by 2 in, and above 26 in by 4 in. e figures in Tables 1, 2 are based on first-class short-lap belting, made from backs of oak-bark tanned leather, run under ordinary conditions and on pulleys of medium and l size. When the driven pulley is smaller, the power transmitted will be as much than the tabulated values as that part of the surface of the driven pulley which is red by the belt is less than half its surface.

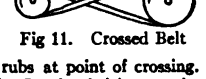

Fig 11. Crossed Belt

ubber belts consist of several thicknesses (plies) of canvas covered with ber. They can be used in damp or wet places, or in drives exposed to the osphere or to acid fumes.

uality of rubber determines grade of the belt, new rubber being better than reclaimed luct. Strength depends upon the wt of canvas used, which is given in oz per sq yd of

AS BELTS are by sewing plies nvas together; n belts by a ing process as th, animal fiber used in some In using this

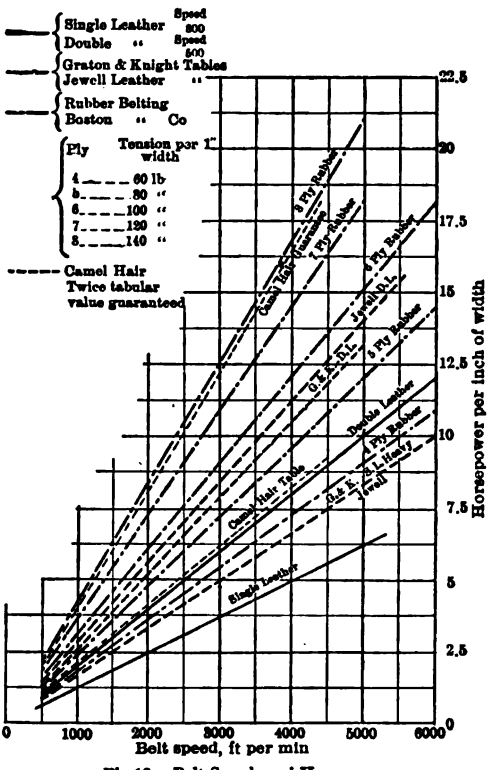

Fig 12. Belt Speeds and Horsepower

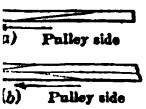
of belting the tension must be the same over the entire width, otherwise the belt ot run true. CAMELS-HAIR BELTING is guaranteed to transmit twice the power of a leather belt, based upon the increased coeff of friction and strength of belt.



13. Scarf Joints, Leather Belt

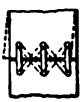


Fig 14. Belt Lacing

Belt fastenings. For leather belting, joints are made by scarfing and gluing the ends together, making an endless belt. Some machines are designed to be shifted on their frames to take up slack, but when the limit is reached the belt joint must be made over. ingle leather belts the joint should be as in Fig 13 *a*; for double belts, as in Fig 13 *b*. per belting can be similarly spliced. After the surfaces are covered with a rubber nt and allowed to dry they are stitched together with narrow rawhide lace. LACING ld have uniform tension; it is straight on pulley side but crosses on the back; for ow belts, the holes are in one line; for wider, they may be staggered. In lacing a the 2 ends must meet square and in line; if offset, as shown by dotted lines, Fig he edges will be damaged. Metal fasteners are good and are made in many desi- canvas and woven belts, the maker generally recommends some special type,

adapted to his own belting. In the fastener shown in Fig 15 *b* the wire is inserted by a special machine, the ends being held together by a rawhide pin. It is a hinge joint and can be readily taken apart and replaced.

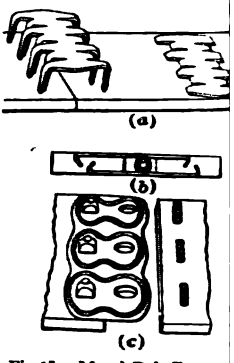

Fig 15. Metal Belt Fastene

3. Pulleys

Pulleys for belt drives are of C I, wood, fiber, or pressed steel. C-I pulleys are solid, or in halves bolted together. A solid pulley must be installed by slipping it over the end of the shaft; split pulleys can be set anywhere on the shaft by bolting them in place.

Principal dimensions for ordering pulleys are bore, diam, width of face, and size of keyway (Fig 16). The face may be crowned or flat (Fig 17). With a CROWNED PULLEY, if the tension is not equal on both sides of belt, or the shafting is slightly out of line, the belt will seek the highest veloc, which is at the middle of the face, and is thus made to run true. Crowning is generally about ⅛ in per ft of width; if excessive, it damages the belt by overstret ing it in the center. Flanges on the pulley face to keep the belt from running off sh be avoided, as they wear the edges of the b If the belt becomes slack it may ride up on t flange and tear. Untrue running of belts is cau by unequal tension or poor alinement of shaft Machinery that must be started and stopped fr quently is sometimes fitted with crowned PU AND LOOSE PULLEYS, the belt being shifted fr one to the other to start or stop the machi The driving pulley has a flat face, and a wi equal to the combined widths of the 2 driven pulleys. BELT SHIFTER should be placed on the side where the belt leads on to the pulley. Very wide C-I pulleys may have double spokes or arms (Fig 18). C-I pulleys are heavier than other types. They vary from 3-in diam and 2-in face to 120-in diam 60-in face. (For details, see catalogues.) Solid C-I pulleys for single-thickness be the cheapest. Split C-I pu cost about 50% more for si sizes, to about 20% more or m dium sizes. C I with the i scale attached withstands s of acid fumes or dampnes be than ste wood. Fa STEEL PU (Fig 1 made in h with d sets of a when nece sary. Sizes vary from 6-in diam by 2-in face to 120-in diam by 36-in face, prices var ing about the same as C-I split pulleys for single belts. Fig 20 shows a set of bush which adapts this type of pulley to several sizes of shaft. WOODEN PULLEYS are made gluing together strips of wood so arranged as to avoid warping. They should not b used in damp places. They are light in wt, and have the same advantages as th

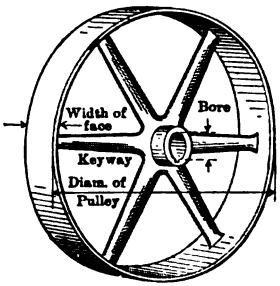

Fig 16. Cast-iron Pulley

Fig 20. Pulley Bushings

ɔl-steel pulley. Sizes are from 3-in diam by 3-in face to 120-in diam by 24-in face 21, 22). Prices of wooden pulleys for double belts aver slightly less than solid C-I ys. Catalogues give information as to special types and sizes. If the coeff of friction

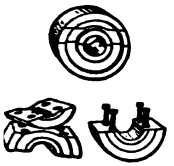

Fig 21. Small Wooden Pulley

Fig 22. Large Wooden Pulley

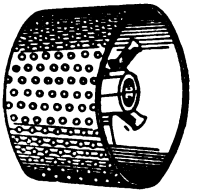

Fig 23. Pulley with Inserts for High Coeff of Friction

ɔe increased, the tension on tight side can also be increased, and more power trans-ɔd; hence, the pulley face is sometimes covered with leather, canvas, or cork inserts 23), increasing the power transmitted for the same drive.

4. Shafting, Hangers, and Bearings

ıafting is of steel, turned and ground, or cold-rolled. The latter has a hard surface, h, if damaged by the cutting of a keyway, may warp the shaft. Shafting is carried ɔck in sizes from 3/16 to 1.5-in diam, in lengths from 1 to 24 ft, and from 1 9/16 to 7 in ., in lengths from 5 to 24 ft. Diam always increases by 1/16 in. Where longer shafts equired, stock lengths are joined by couplings.

ıngers and bearings. Shafting is ed in bearings mounted in adjustable ers attached to the ceiling, walls, floor, ɔsts of a building. Special fittings are ired for steel-frame buildings. Hangers f C I or pressed steel. Fig 24 is a ceil-anger which can be reversed and made or stand. In Fig 25 the bolts *c* pass ıgh slotted holes to permit adjust-t; the bearing can be raised or lowered crews *d*, which support it. The bear-n Fig 26 has a spherical seat at *a*, for ng in any direction about its center. lower cap *b* (Fig 25) can be removed, box taken out, or shafting removed, out interfering with the hanger. Shaft-can be assembled on the floor, hoisted into position in the hangers, and bearings caps readily put on; convenient for heavy work. Boxes should be ring-oiled and dustproof, to minimize attendance. The points for ordering hangers are: style of hanger, drop or distance from center of shaft to the base (Fig 24), and diam of shaft. When in places difficult of access, shafting and bearings are apt to be neglected. When hangers are attached to ceiling beams, the spacing of these determines the distance between bearings; 8 to 10 ft is considered good spacing; if greater, heavier shafting should be used to prevent bending. Length of bearings is given ɛrms of diam of shaft; for diam less than 2 3/16 in bearings are 5 diam long; for heavier ting, 4 diam long. Shafting is subjected to torsion, due to the power transmitted, to bending, due to wt of the pulleys, its own wt, and the wt and tension of the belts. pulleys should be as close to the hangers as possible, and heavy drives placed near the ıt where the power is received. For good service, shafting should be carefully alined, ı a small end play (say 1/8 in), and with collars to prevent any excess end motion. ɛre the power is received, collars should be placed on both sides of one hanger, leavir

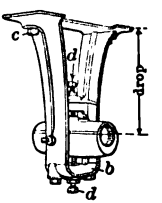

Fig 24. Ceiling Hanger

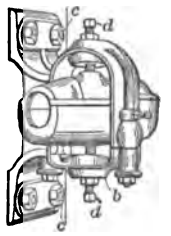

Fig 25. Adjustable Post Hanger

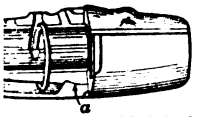

26. Hanger with Spherical Seat

the ends of the shaft free to expand and contract with temp changes. Motors driving shafting in dusty places can be enclosed, and a slight increase of air press above atm maintained on the inside, to prevent entrance of dust. BEARING PRESSURES are determined per sq in of projected area (diam × length of bearing). The aver allowable press, varying with load conditions, speed, lubricant, and method of lubrication, is about 60 lb per sq in of projected area.

5. Rope Drives

Hemp or cotton-rope drives are of two kinds: continuous or American, and multiple or British. AMERICAN SYSTEM. The rope is wound around the pulleys as many times as the power to be transmitted requires; it then passes over a tension carriage (see below), which keeps the rope at constant tension and returns the last wrap to the first groove of driving sheave. This drive has only one splice, which is the weakest part of the rope. Breakage of the rope causes complete shut down, usually avoidable by careful inspection. This system is best for vertical or angular drives, and can be used for heavy powers with short center distance. BRITISH SYSTEM has separate ropes for each loop, and hence has as many splices as ropes. Maintenance of constant tension in all the ropes is difficult but important. If 1 or 2 should fail the others will transmit the power until repairs are made. Low tension lengthens life of the drive, which should average 8 to 10 years.

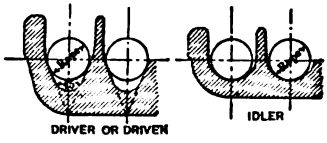

Fig 27. Sheave Grooves, British Rope Drive

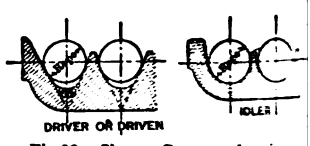

Fig 28. Sheave Grooves, American Rope Drive

Sheaves and rope. Fig 27 shows shape of grooves for main sheaves and idler, of the English system; Fig 28, for the American system. Grooves must be accurately machined with surfaces free from imperfections; rough holes cause rapid wear on ropes. For necessarily heavy, the sheaves act as fly wheels for variable loads, and should be well balanced. Minimum sheave diam is 36 times rope diam; 40 times is better. Rope must not touch bottom of grooves of driver or driven sheaves, otherwise no wedging action occurs to cause the rope to rotate on its axis and so produce uniform wear.

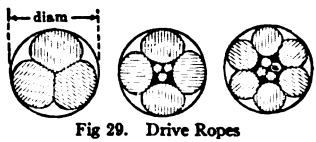

Fig 29. Drive Ropes

Cotton ropes are softer than hemp, cost more, and are more used in Great Britain than in U S. Hemp transmission ropes are laid with internal lubricant to reduce wear. Manila rope has 3, 4, or 6 strands (Fig 29). Diams from 0.75 to 2 in increase by ⅛ in; from 2 to 2.5 in by 0.25 in. (For strengths and wt of hemp rope, see Sec 12, Art 13.) To lie properly in sheave grooves, splices must not increase the rope diam. Strength of a good splice is about 85% that of the rope.

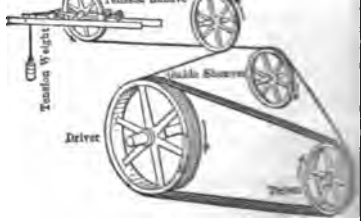

Fig 30. American Rope Drive

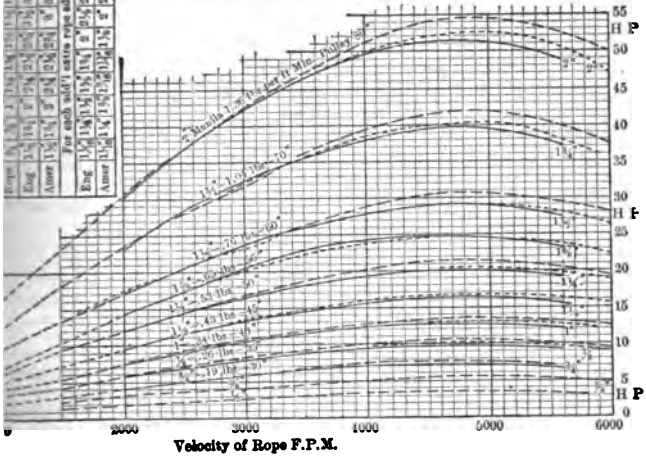
In the American drive (Fig 30), constant tension is maintained by a TENSION CARRIAGE, to compensate variation in length, from stretch or shrinkage due to moisture. A tension carriage will take care of 3 000 to 3 500 ft of rope.

ower transmitted by rope drive depends upon the same elements as for belting. friction between the ropes and sides of grooves can be increased by an increase of tension, and the difference between the 2 tensions and centrifugal force is the pull in lb. Rope speed is generally the same as for



$$\text{ıate breaking load, lb} = \begin{cases} 7\,000\,d^2 \\ 720 \times \text{circ'm rope}^2\text{(in)} \end{cases} \qquad \text{Weight of rope, lb per ft} = \begin{cases} 0.34\,d^2 \text{ to } 0.33\,d^2 \\ 0.039 \times \text{circ'm rope}^2\text{(in)} \end{cases}$$

$$\text{er working load} \quad \text{"} = 20 \times \text{circ'm rope}^2\text{(in)} \qquad \text{Diam of a rope} = \text{diam of circumscribing circle}$$

$$\text{(max tension)} \quad = 800d^2 \qquad \text{Circ'm "} \quad \text{"} \quad \text{"} = \text{circ'm "} \quad \text{"}$$

31. English (Multiple) Hemp Rope Drives (C. W. Hunt Co, broken lines; G. V. Cresson Co, dotted lines; Rice & Sargeant, full lines) L. DeG. Moss

ng; but, since rope weighs less than belt, the tension can be increased at high ds to offset effect of centrifugal force; 80 ft per sec is an aver speed.

riving force is $P = T_n - T_0$, where T_n = tension on tight side, and T_0 is the ltant of the tension on slack side (taken as 0.5 P) and centrifugal force C. Hence, ower may be written, $P = T_n - (C + 0.5\,P)$, reducing to $P = \frac{2}{3}(T_n - C)$, and the = $\frac{2}{3}(T_n - C) \times V \div 33\,000$, where V = rope veloc, ft per min. The expression centrifugal force is $C = Wv^2 \div 32.16$, W being the wt of rope per ft and v the veloc, er sec. With fixed rope speed and min diam of sheave it is more difficult to design than belt drives. If the desired rev per min can not be obtained with a certain rope n, the rope diam may have to be reduced, so as to use a smaller sheave. To trans- the same power, this requires more ropes, increasing wear and maintenance. It is l practice to use few ropes of large diam; 1.75-in rope is a good commercial size.

omparison of power drives. Gearing is used for minimum center distances; it gives a tive drive, but is noisy. Chain drives are positive, and special forms can be run at speeds; center distances are greater than for gears, less than for belts. Belts can hifted from one pulley to another, can be run at high speeds or at any angle, require l alinement of shafting, are not noisy, but produce electricity, which is sometimes ob- ionable. Rope drives, used for max center distances, are quiet in operation, produce electricity, do not require accurate alinement of shafting, can be run at any angle, spy less space than belts, and are cheaper than belting for heavy power and long er distances.

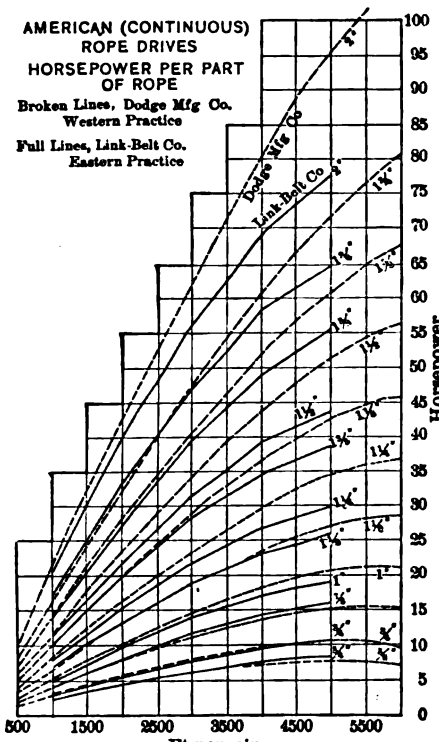


Fig 32. (L. DeG. Moss)

Wire-rope drive (Fig 33), consisting of a single loop of wire rope around a pair of pulleys, can be used for distances of 70 to 400 ft between sheave centers. The sheave grooves are "filled," and the rope should not touch the sides of the grooves, thus requiring good alinement.

Driving power depends upon coeff of friction between rope and sheave filling. (For wire ropes, see Sec 12, Art 11.) 7-wire rope will stand more wear, but requires larger pulleys. Steel rope is stronger and has a longer life, but the size can not be reduced due to the wt required; a small rope must have more tension and damages the pulley lining. Bending stresses (Sec 12, Art 14) generally exceed those due to direct pull. Speed limit is 5 000 ft per min. If the rope lashes at high speed the direct tension may be momentarily doubled, and if the sheaves are small, the bending stresses plus the tension may strain the rope beyond the elastic limit.

Sheaves should be as large as practicable, to give high rope speed and hence permit use of min diam of rope. Fig 34 shows sheave groove and filling. Filling consists of alternate blocks of leather and rubber; rubber has high coef of friction, while the leather has resisting qualities. Hard-wood blocks are sometimes used. 5 000 ft per min rim speed is about the safe limit for C-I sheaves or for the filling.

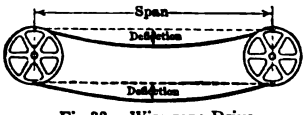

Fig 33. Wire-rope Drive

Fig 34. Filling for Wire-rope Drive Sheaves

Sheaves must be accurately balanced, to prevent lashing of the rope. At less than 70 ft center distance, tension must be excessive, increasing wear on rope and filling. For spans greater than 400 ft, multiple loops may be employed. Where there are sudden variations in load, a flywheel can be attached to the sheave shaft. For changing direction of the drive, bevel or friction gears are used. The heavier the rope, the greater the tension and farther apart may the sheaves be placed, with smaller sag or deflection. Makers advise a sag of 1/30 the span in both ropes when idle; in operation, the sag on tight side is about 0.02 the span and on the slack side 0.04. This makes the tension

ıbout 2 : 1; or difference in tensions may be computed by taking the wt of 1 rope en sheaves and multiplying by 3. The hp can then be found: hp = $T \times V \div$), T being difference in tensions and V veloc, ft per min. No deductions are made ntrifugal force or bending stresses, as they are negligible under usual conditions. sheaves may be used to prevent the rope from striking obstructions. When on llowing side, they are 0.5 the diam of the driver or driven wheel; if in the middle ɔan, the tension and power transmitted will be halved. Tightener sheaves may be l on short spans, but are not recommended. Sheaves are sometimes mounted on ɔle bearings, for taking up slack without resplicing. Catalogues of makers give of hp transmitted, center distances, diam of sheaves, and rev per min for differ- :e ropes.

6. Lubricants

quirements. Lubricant must have sufficient BODY at the probable temp ıich it will be subjected to prevent it from being squeezed out by press be- ı bearing surfaces; it must not decompose nor evaporate at ordinary work- :mp; it must contain no acid which may injure bearing surfaces; its coeff :tion must be low; it must be as fluid as is consistent with the required ; and it must not freeze at any temp to which the bearing may be exposed.

dinary lubricants: animal fats, vegetable and mineral oils, flake graphite, tone, powdered mica.

mal fats or oils are often used for bearings subjected to low temp, but are generally with mineral oils. They decompose at moderate temp and set free acid. Vegetable e used where the bearing press is light and temp low. Mineral oils are obtainable practically all conditions of lubrication; they do not easily decompose and contain d. Greases are mixtures of mineral oil and animal or vegetable soap; useful for ıoving bearings under heavy press.

ıid lubricants, used alone, fill the pores of the bearing metal and form a film They are commonly mixed with oil or grease, and generally improve ation. They must not be used for ball bearings, as they build up a surface : ball race which often splits the bearing.

ting lubricants. The value of ordinary tests are relative rather than absolute, ils, showing approx the same characteristics, will probably serve equally well in me bearing. Oils are tested for the following characteristics. Special machines :d for coeff of friction tests. Other tests are for adulteration and presence of acids. ITY, or degree of fluidity, is a measure of the body of an oil. It is determined :osimeters. Nearly all operate on the principle of finding the time required for a :olume of oil to flow through an orifice. Their design varies greatly, and 2 differ- truments may give widely different results for the same oil. Viscosity is generally :ed as specific or as relative viscosity (Table 3), which denotes the relation between ıes required for the same volume of oil and water to flow through the orifice. Tests de at different temps. FLASH POINT is the temp at which an oil will give off enough :o ignite and flash, when a flame is held over the surface. The heating should be ɔwly. Types of apparatus are the open cup and closed cup. The closed cup has ıing in the cover, closed by a slide. As the oil is heated the slide is periodically d, and a flame inserted until the flash point is reached. During tests a thermom- hung in the body of the oil. BURNING POINT is the temp at which an oil will give ugh vapor to ignite and continue to burn. CHILL POINT is the temp at which an ses. Best determined by placing the oil in a test tube with a thermometer. The ben frozen by an ice and salt mixture. After freezing the test tube is removed ıe ice and the temp observed at which the oil melts. FRICTION TESTS are made by machines, designed to reproduce working conditions, and to measure the temp of and coeff of friction. The speed and press between bearing surfaces may be t will. The simpler machines give only comparative results, but valuable data ten obtained from specially designed apparatus.

ıgtion of adulterants. High-grade oil is sometimes adulterated with low-flash oil, which is detected in flash-test apparatus. Presence of vegetable or animal

oil in mineral oils is determined by mixing a sample with a solution of sodium or pot sium hydroxide and heating to about 200° F. Animal or vegetable oils will saponi and separate from the mineral oil. Presence of mineral oils in animal or vegeta oils is determined by the same process, as the mineral oil will not saponify. Aci detected by litmus paper.

Table 3. Characteristics of Lubricating Oils

Kind of oil	Specific viscosity, 70° F	Specific grav, water=1	Flash point, deg F	Burn point, deg F
Heavy engine and machine	185	0.875	400	445
Ordinary engine and machine	180	0.873	410	460
Light machine	100–150	0.870	400	445
High-grade cylinder	175–200	0.903	600	650
Ordinary cylinder	185	0.899	570	625
Gas engine	300	0.893	320	355
Automobile cylinder	195	0.877	430	485

Most of the above oils have a chill point slightly below freezing point of water may be obtained the chill point of which is considerably lower.

Selection of lubricants. For engine cylinders using high-press steam, h grade cyl oil; for engine cylinders using steam below 100 lb press, second-gr cyl oil; for stationary gas engines, a heavy oil with high flash and burning po (it should preferably have a liquid base); for air compressors and high-s internal combustion engines, a liquid-base oil with a relatively low viscosity a high flash point. Engine and machine oils are sold in many grades to su conditions. For slow-moving bearings under heavy press, use grease. If press is exceptionally heavy, add graphite to the grease.

7. Piping

List sizes of welded W-I or steel pipe indicate the nominal inside di Actual diam varies considerably from the nominal, especially in standard wt of small sizes. Outside diam of all weights is the same, so that the threads be uniform for same nominal size. Added thickness of metal reduces internal diam. Ordinary welded pipe is of mild steel. If iron pipe be desi it should be specified. Tubes are listed according to their actual outside di Pipe is regularly supplied in random lengths, from 18 to 22 ft, threaded at ends, and 1 coupling is furnished with each length. An extra charge is ma pipe in equal lengths. Prices vary with the metal market, and the plan va

Approx discounts from list prices in New York, 1915: standard pipe (slightly higher in small sizes and lower in large); extra-heavy pipe, double extra-heavy, 43%; spiral-riveted pipe (N Y, 1916), 40%; screwed fittings, standard wt, 70%; extra-heavy and double extra-heavy screwed fi 65%; flanged fittings, all wts, 65%. Discounts on valves are from 40 to Prices on pipe coverings and insulating material are practically net.

In the following tables a fairly complete list of pipes and fittings is given, but va and cocks are omitted as they are made in too great variety to be listed here. Th catalogues should be consulted regarding them.

Table 4. Line Pipe, for Oil, Gas, and High-press Mains

Table 5. Root's Spiral-riveted Pipe

t and asphalted pipe is in lengths of 25 ft or less, galvanized in lengths of 20 ft.
pprox for black pipe only; asphalted and galvanized weigh 10 to 20% heavier.
s, $ per linear ft, with plain, crimped, or sleeved ends.
es when furnished are included in linear measurement.

ra strong and double extra strong will be shipped in random lengths and plain ends otherwise ordered. For pipe fitted with threads and couplings, extra charge will ıde above regular. For cut lengths, extra charge will be made above random. ılvanized or asphalted, extra charge will be made above black.

10. Springs

mulas relating to springs are based on torsion formulas, modified according to of spring and cross-section of the wire or rod. The following brief notes relate ially to springs of hoisting cages.

lical **spring**, of round wire, wn in Fig 35; Fig 36 illus- its action. A load, P lb, is ed by a cord to the rim of a , of a diam D = mean diam spring coils, and produces n in the rod. A line AB, ally straight, becomes a AC, length of rod being l. between AB and AC is the of shear ϕ, and angle BOC s the angle of twist. For rium the external and in- moments must be equal,

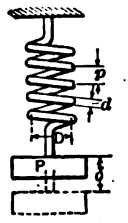

Fig 35. Helical Spring

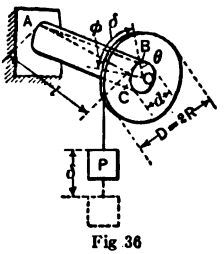

Fig 36

(Fig 36) $P\frac{D}{2} = f_s Z_p = f_s \frac{\pi d^3}{16}$, where Z_p equals section modulus (Sec 43, Art 4) d from the polar moment of inertia, and d equals diam of wire or rod. From the on, the load P which the spring will carry can be determined for any given fiber f_s by transposition, $P = \frac{2\pi d^3}{16 D} f_s = \frac{\pi d^3}{16 R} f_s$, all dimensions being in inches. The of a coil of the spring is generally taken as πD; accurately, it is $\sqrt{(\pi D)^2 + p^2}$. On ng the load, the rod is twisted through an angle θ; or through a length of arc red on the circumference of $D = \delta$, which is the moment of the weight P. If the ce from B to C measured on the rod circumference = x, then

$$\frac{x}{l} = \frac{\text{Shear stress}}{\text{Modulus of rigidity}} = \frac{f_s}{G}.$$

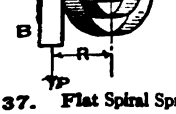
$\phi = x + l$ and angle $\theta = x + r$ or $2x + d$; hence, $\theta = 2 f_s + Gd$, and $\delta = R\theta l = Gd$. Since $f_s = 16 PR + d^3$, $\delta = 32 PR^2 l + Gd^4$, which gives the deflection of ing, where $l = 2\pi Rn$, if n = the number of complete coils. The resilience = 0.5 oviding the spring is not too open.

rectangular wire or rod, the max stress occurs at centers of the longer sides. If b = ss and h = width of section of wire,

$$I_p = \frac{b^3 h^3}{3(b^2 + h^2)}, \text{ and } Z_p = \frac{b^3 h^3}{3\sqrt{h^2 + b^2}}.$$

ing the same analysis, $P = \frac{f_s}{3R} \frac{b^3 h^2}{\sqrt{b^2 + h^2}}$, and $\delta = \frac{3 PR^2 l}{G} \frac{b^2 + h^2}{b^3 h^3}$.

e of square section, $b = h$, $I_p = b^4 \div 6$, and $Z_p = b^3 \div 3\sqrt{2}$.



37. **Flat Spiral Spring**

Fig 38. Round and Flat Helical Springs

spiral spring (Fig 37). In this the center is fastened to an arbor, the other end tached to the framework. The formulas are correct if the spring winds uniformly **center** remains the center of gravity. If the load is applied at B, the gr **stress** may occur at a point diametrically opposite A, or at the spindle if t

ature is great. For the first condition the external moment $= P \times 2R$ and $f = 2Pr \div$ $= 12\,PR \div bh^2$; in the second case, $f = 6\,PR \div bh^2$. The load is $P = fbh^2 \div 12\,R$ (first case), or $fbh^2 \div 6\,R$ (second case).

From the theory of the elastic curve, the angle of deflection $\beta = PRl \div EI$, and $\delta = \beta R = PR^2l \div EI = 12\,PR^3l \div Ebh^3$, and resilience $= 0.5\,PR^2l \div EI$, and $I = bh$ $\div 12$.

Round and flat helical springs (Fig 38). For a spring subjected to a force P, tending to twist the spring at a radius R, the load $PR = fZ = fnd^3 \div 32$ for the circular section, and $PR = fbh^2 \div 6$ for the square section; also $\delta = 64\,PR^3l \div Ed^4$ for circular section, and $\delta = 12\,PR^3l \div Ebh^3$ for square section; the resilience being determined as above.

1. Definitions, Units, and Standards

Potential (E or V), or DIFFERENCE IN POTENTIAL between two points, is oretically the work required to move a unit quantity of electricity from one nt to the other. It is analogous to difference in pressure, or head, of a current water The practical unit is the (International) VOLT, or electrical pressure ich, when steadily applied to a conductor the resistance of which is 1 ohm, l produce a current of 1 ampere. Difference of potential is measured in prac- by a VOLTMETER (Art 4). For comparison and calibration the Weston rmal Cell is used, the electromotive force (e m f) of which is 1.0183 volt at C. These cells are calibrated by Bureau of Standards, Washington. A livolt is 0.001 volt.

Current (I) expresses the quantity of electricity flowing past a given point 1 sec; it is analogous to gal per sec of a current of water, or to the miner's h. The practical unit is the (International) AMPERE, or the unvarying tric current which, when passed through a solution of $AgNO_3$ in water, in ordance with standardized specifications, deposits silver at the rate of 0.001118 per sec. Current is measured by an AMMETER (Art 4). A milliampere is 01 ampere. DIRECT CURRENT (d c) is officially one which always has the ne direction, though it may pulsate in value; but the term is po

applied to a unidirectional current of constant value, officially called a CONTINUOUS CURRENT (c c). ALTERNATING CURRENT (a c) is one which changes its direction and amount in regularly recurring periods.

Resistance (R) in an electric circuit is similar to friction in mechanics. It is the property by which a circuit limits the amount of current caused by a steady voltage. The (International) OHM is the practical unit of resistance and is the resistance offered to an unvarying electric current by a column of mercury, at temp of melting ice, which is 14.4521 gm in mass, of constant cross sec and a length of 106.3 cm. Resistance is usually determined by computing the ratio between volts and amperes in a circuit according to Ohm's law (Art 2).

Power unit is the watt or kilowatt (kw). A watt equals 10 million units of power in the centimeter-gram-second system, and in practice equals the product of 1 volt by 1 ampere, or is the rate of expenditure of energy by 1 ampere in a circuit of 1 ohm. A KILOWATT is 1 000 watts; a horsepower (U S) = 746 watts.

Energy. The theoretical unit is the JOULE, which is 10 million ergs; in practice, equal to 1 watt times 1 sec. Commercial unit is the kilowatt-hour (kw hr) equal to 3 600 000 joules. A circuit taking 10 amperes at 100 volts receives 1 kw of power, or 1 kw-hr of energy per hr; hence 1 kw-hr = 2 655 000 ft lb.

Coulombe is the unit of quantity of electricity (corresponding to a gallon of water) or the quantity transferred in 1 sec by a current of 1 ampere.

Capacity is the ability of an electric circuit to store energy in the space between conductors, measured in coulombes or quantity of electricity. A condenser is a device to provide capacity. FARAD (C) is the unit of capacity; or the capacity of a condenser which will be charged to a potential of 1 volt by 1 coulombe of electricity. A microfarad is one-millionth of a farad.

Maxwell (ϕ) is the unit quantity of magnetic flux, and is equal to 1 line of force.

Gauss (B) is the unit of magnetic flux density, and is equal to 1 line per sq cm, or 1 maxwell per sq cm.

Gilbert (F) is the unit of magnetomotive force (m m f), and is that m m f which will produce 1 line or 1 maxwell in a path in air having a cross-sec of 1 sq cm and a length 1 cm. One ampere turn = 1.257 gilberts.

Oersted (S) is the unit of magnetic reluctance, and is the reluctance of that path which requires 1 gilbert to set up a flux of 1 maxwell. Reluctance in a magnetic circuit is similar to resistance in an electric circuit.

Inductance is a characteristic of an electric circuit by which the circuit opposes any change in value of the current. It is similar to mass and inertia in mechanics. A variation in current produces an ELECTROMOTIVE FORCE (e m f) which opposes the change in current (Art 2).

Henry (L), the unit of inductance, is the inductance of a circuit in which a variation of current of 1 ampere in 1 sec will induce an e m f of 1 volt.

Hysteresis. When iron or steel is magnetized by an electric current, the value of magnetic flux does not vary directly with the current. An increasing current does not produce the same flux for a given current as a decreasing current. This lagging of the flux behind the magnetizing force is called hysteresis, and may be considered as the effect of friction between the molecules of iron which, in aiming themselves with the flux like small magnets, rub against each other. Hysteresis causes loss of energy and heating of the iron when the direction or magnitude of flux is changed. If the magnetizing force varies through complete cycles, positive and negative, the power lost in hysteresis is:

$$\text{Watts} = k_1 f V (B_m \div 1\,000)^{1.6} \times 10^{-6}$$

where $k_1 = 6$ to 18, depending upon quality of iron; f = frequency in cycles per sec, V = volume, cu in; B_m = maximum magnetic density in lines per sq in.

Eddy currents are local currents induced in any conducting material located within the influence of any varying magnetic field. The term is especially applied to currents

ıp in the iron core of a machine, or in a conductor carrying an a c. These currents e heating and loss of power and energy.

ffective resistance of a circuit carrying an a c is found by dividing the total loss in s due to the combination of true resistance, eddy currents and hysteresis, by the ıre of the effective value of the current.

eries. Two circuits are in series when the same current passes through ı successively.

hunt. A circuit is in shunt, in MULTIPLE or in PARALLEL, with another n they form a divided circuit, so that a part of the total current passes ugh each, while the potential across them is common.

onstant potential circuit is one across which the potential is kept as nearly ossible constant, irrespective of the current flowing. It infers a supply ı a circuit of low resistance. Most house lighting (incandescent), motor ly, and transmission systems are of constant potential type.

onstant current. Certain systems of lighting by arc lamps require con- t value of current in all the lamps, which are therefore connected in series the voltage across the whole circuit is varied to suit the number of lamps peration. A special type of generator or transformer is required. In pe the Thury system of long-distance transmission employs a constant d c, voltage generated being made to vary with the load.

nductance (G) of a circuit is that quantity which, if multiplied by the voltage, will total current if voltage is unvarying, and which will give the component of current ase with voltage ($I \cos \phi$) if voltage is alternating. For d c, conductance is the recip- of resistance. For a-c conductance, see Art 7. Conductance is used in analyzing mul- circuits. 1 volt applied to a circuit of 1 MHO conductance will cause 1 ampere to flow.

.ting of an electrical machine is the load in kw which it will give for a fied period of time without injury to itself. There are several limitations e output, but the one most frequently met and inferred is injury to insula- by the heat developed. The limit is the temp of the hottest part of the ine, and the allowable temp depends upon character of the INSULATING RIALS. These are divided into 3 classes: (*a*) cotton, silk, and other fibrous ials, not so treated as to increase their heat-resisting qualities; (*b*) simi- aterials, but treated and impregnated, including enameled wire; (*c*) mica, tos, and other materials capable of resisting high temp. Temp of machines ially determined by thermometer or by resistance measurements. Since r method gives the temp of the hottest spot, it has been agreed to assume mp of the hottest part as 15° C higher than indicated by a thermometer e surface, and 10° C hotter than indicated by resistance measurement. of surrounding air (ambient temp) influences directly the temp of the ine. Provision must be made that, when the air is at its highest possible (assumed at 40° C), the machine will not become excessively hot. This c by specifying that the rise in temp above surrounding air shall be such if operating in a room of 40° C, its hottest spot shall not exceed certain

ble 1. Temperature Conventions (Standard Rules of Am Inst Elec Engs)

ss of ation	Highest permissible temp	Limiting temp by thermometer	Limiting temp rise	Limiting temp by resistance	Limiting rise by resistance
a	95° C	80° C	40° C	85° C	45° C
b	105	90	50	95	55
c	125	110	70	115	75

established values. CONTINUOUS RATING is the load in kw which a machine will carry continuously without exceeding the above temp rise. INTERMITTENT RATING, or short time rating, is the load in kw a machine will carry for a specified period (up to 2 hr) without exceeding these limitations. Unless otherwise specified continuous rating is understood (Art 6).

2. Principles

Electric circuit. OHM'S LAW: $E = IR$, where I = current, amperes; E = e m f or difference of potential, volts; R = resistance, ohms. Used for solution of all simple d-c circuits and for a-c circuits having no reactance. For an a-c circuit having reactance, $E = IZ$, where I and E are effective values and Z is impedance in ohms (Art 7).

Kirchoff's laws are for solving any combination of series, multiple, or series-multiple circuits. FIRST LAW, for series d-c circuits: $E_0 = E_1 + E_2 + E_3$, where E_0 = generated e m f, E_1 = counter e m f (motor), and $E_2 = IR_2$, etc, are the drops in voltage in different resistances (Fig 1). Special case $R_0 = R_1 + R_2 + R$. SECOND LAW (for multiple d-c circuits): the algebraic sum of all currents meeting at a point = 0 (Fig 2). $I_0 = I_1 + I_2 + I_3$, where I_1 may be found by $I_1 = E \div R_1$, whence

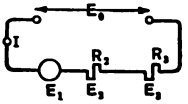

Fig 1. Series Circuit

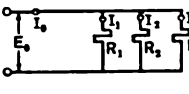

Fig 2. Multiple Circuit

$$I_0 = \frac{E}{R_1} + \frac{E}{R_2} + \frac{E}{R_3}; \quad \text{or in general} \quad \frac{1}{R_0} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$$

Magnetic circuit is calculated similarly to electric circuit: $\phi = \frac{\text{m m f}}{\text{reluctance}}$ where ϕ = flux in maxwells, m m f is in gilberts and reluctance S is in oersteds $= l \div \mu A$, where l = length of path, cm; A = cross-sec of path, sq cm; μ = permeability of the material, varying from 1 for air to 3 000 in some steel

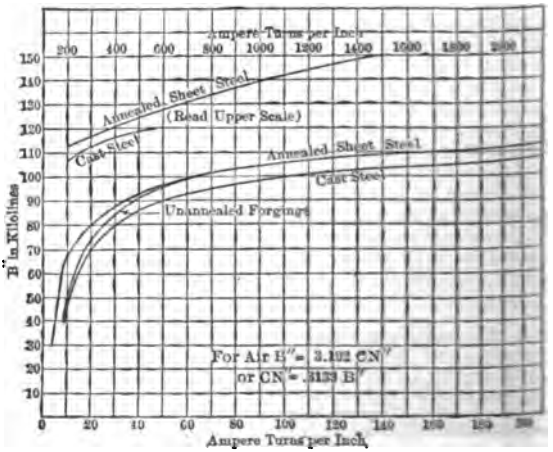

Fig 3. Typical Magnetization Curves

Permeability. Since μ varies greatly with different materials, and with different densities in same material, it is more practical to calculate a magnetic circuit by use

gnetization curves, which show relation between m m f per unit length of path and ensity in maxwells or lines per sq cm. Such a curve must be made for each different ial used. In U S it is customary to plot the magnetization curve between the re turns per in length of path and maxwells or lines per sq in (Fig 3). To determine irrent to produce a given flux, divide number of lines of flux by cross-section of t in sq in, and find required magnetic density in lines per sq in. Referring to magtion curve (Fig 3) of the particular material to be used, the number of ampere per in of path is obtained for this particular density. Multiplying this number by ı of path (in) gives total ampere turns required, which may be divided into any er of amperes or any number of turns, the product of which will give the required er. For a path in air, or in any non-magnetic material, the ampere turns per 2.313 times the density in lines per sq in.

ce on a conductor. Experiment shows that if a conductor carrying a current having a length l is placed in the magnetic field of density B gausses, at right angles direction of lines of force, a mechanical force will be exerted on the conductor, at angles to the conductor and to the flux, the value of which will be $f = Bli$, where mes, if the other quantities are expressed in c-g-s units. Practical form of this on is $F = 0.89\ Bli\ 10^{-8}$, where F = lb, B = lines per sq in, l = in, I = amperes. elation is basis for calculation of torque of any motor. In this case l must be the of conductor in the active field only. The pull of any magnet is given by equation,

$$P = B^2A \div 72\,134\,000$$

P = lb, B = lines per sq in, A = cross-sec of core, sq in. This is the case when a tic elements are in contact; when separated, the average gap density must be used.

neration of an electromotive force (e m f). When a conductor is moved nagnetic field so that it cuts lines of the field, an e m f is generated, nually proportional to rate of cutting the flux. When conductor cuts 10^8 lines ec, one volt is generated. If Z conductors are connected in series, as is in practice, $E = Z\phi \div 10^8\ T$, where E = average volts generated and ϕ = ut in T sec. In the armature of any machine the relations are:

Average E of a d-c machine = $(4\ PNS\phi) \div (120 \times 10^8)$

Effective E in an a-c machine = $(4.44\ PNS\phi) \div (120 \times 10^8)$

P = number of poles, N = rev per min, S = turns in series between term- ϕ = flux per pole, maxwells.

3. Conductors

pper is generally used, iron and aluminum being next in importance. gh all metals are conductors, only these 3 are of commercial value, since cost is reasonable and loss of energy is low. SILVER is the best conductor, too expensive for practical use. COPPER is nearly as good as silver, and t economically. ALUMI- next; in the form of solid is as cheap as copper, but uniformity in mechanical th. It is better when in of stranded cables, but n more expensive than r of equal conductivity. and STEEL approach cop- economic value, and for conductors are preferable se of their mechanical strength. An INSULATOR is a material used to prelow of current, but division between insulators and conductors is not sharp; ulators conduct some current. Common insulators are air, glass, porcelain r, cotton, paper, and dry wood.

esistance of any conductor is given by: $R = \rho L + A$, where R = resistance, s; L = length of conductor, ft; A = cross-sec of conductor, circular mils; pecific resistance, or resistance of a conductor of unit cross-sec and length. igh the cm and sq cm are the more scientific units, it is convenient to use ircular mil for unit of cross-sec and the foot for unit of length, as adopted for nercial wires. A circular mil is the area of a circle having a diam of one mil 1 in). A circle 1 in diam has an area of 1 000 000 circ mils, and 1 sq in = 000 circ mils. Hence, in above equation, if length be 1 ft and A = cross- circ mils, then ρ has values given in Table 3.

ecific resistance ρ varies directly with the temp. Table 3 gives a constant letermining the percentage of increased resistance per deg C in excess of . General law of increase in resistance of copper with rise in temp is $R_0 (1 + 0.0042\, t)$, where R_t = resistance at any temp, $t°$ C; R_0 = resistance C; t = temp above 0° C.

ire gages. Standard classification of wires in the U S is the Brown and pe or American wire gage (Table 4).

& S gage sizes have definite relations, readily remembered: A wire 3 sizes larger another has nearly half the resistance, twice the area, and twice the wt per unit h. Thus, No 7 has half the resistance of No 10. A wire 10 sizes larger has 0.1 the ance and 10 times the area and wt. No 10 is approx 0.10 in diam, has area of 10 000 nils, resistance of 1 ohm per 1 000 ft at 20° C, and weighs 32 lb per 1 000 ft.

sistance and wt of standard sizes of wire of other materials are found by following ratios: ALUMINUM, multiply resistance given for copper by 1.61 the wt by 0.301. IRON telegraph wire, resistance is 5.96 and wt 0.877 that pper. STEEL wire, resistance is 8.82 and wt 0.883 that of copper.

rmingham wire gage (B W G), also known as Stubbs, is largely used in t Britain and somewhat in this country. Metric system is used in France Germany. Roebling table is used in the U S for steel wires and cables.

Table 5. High-resistance Wires

* Manganin is used in electric meters because of its low temp coef.

4. Measuring Instruments

lenoid. Simplest form of measuring instrument is the PLUNGER TYPE of oid. It consists of a coil of thick wire carrying current to be measured, and t steel plunger which is pulled into axis of coil by effect of the current acting st weight of plunger, or against a spring. Operates with both d c and a c, is not accurate with either. MAGNETIC VANE is a special form of solenoid ument. Inside the coil carrying the current is a thin steel vane, pivoted nter of coil, and a fixed vane of triangular cross-section. When c

flows in the coil, both vanes are magnetized alike and repel each other; hence pivoted vane moves away from fixed vane, moving force being proportional to square of the current. Used both for d c and a c, but its accuracy varies with frequency and wave shape. INCLINED COIL solenoid instrument is very generally used to measure a c. A cylindrical coil of wire carrying current to be measured is set inclined to a spindle or axis carrying a steel vane. When no current flows, the vane is held in plane of coil by a spring. When current flows, the magnetic field is perpendicular to plane of coil and the pivoted vane in moving to set its longer axis in the line of flux, rotates the spindle to which pointer is attached. Force is proportional to square of the current. Used for d c and a c, but is affected by wave shape and frequency. D'ARSONVAL PRINCIPLE, used in almost all instruments for d c, employs a coil of fine wire placed in the field of a permanent magnet suspended so that it can rotate. Current to be measured, or a definite part of it, passes through the movable coil, causing a torque which is resisted by a spring. The force is directly proportional to the current. Only operative with d c, and is affected by stray magnetic fields.

Hot-wire instruments may be used to measure both d c and a c. The current is passed through a wire, which it heats and lengthens. Increase in length is taken up by a spring or weight, the movement of which is proportional to square of current.

Dynamometer consists of 2 coils, fixed and movable, so arranged that their magnetic fields act upon each other. The current, passed through the two in series, develops a torque (as in a series motor) proportional to square of the current. Movement of the coil is resisted by a spring and indicated by a pointer. As no iron is present, this instrument is accurate for d c and a c of all frequencies. The principle is used in the Siemens dynamometer, in some a-c voltmeters and ammeters and in all wattmeters. In wattmeters one coil is in series with the line and the other coil across the load, receiving current through a high resistance proportional to the potential.

Induction-type instruments utilize the fact that, if a coil carrying an a c has within it a piece of copper or aluminum, eddy currents will be induced in the metal, and these will react on the main current giving a force or torque. The torque is proportional to square of current. Instrument operates only on a c, and is affected by varying frequency.

Ammeter operates on any one of above-mentioned principles. Its electric circuit must have very low resistance, and usually the measuring coil carries only a small though definite part of the current. In parallel with working circuit, there is usually a metallic "shunt," which has such resistance that the maximum current to be measured causes a drop of about 50 millivolts (Art 1, par 1) in the shunt. Some meters have interchangeable external shunts, while others have shunts placed inside the case and permanently connected in the circuit.

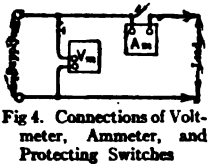

Fig 4. Connections of Voltmeter, Ammeter, and Protecting Switches

When the instrument is used with an external shunt it is sometimes called a MILLIVOLTMETER, its scale being marked in millivolts. An ammeter must never be left connected in the circuit without its shunt. Most ammeters for measuring d c operate on the d'Arsonval principle, as it gives the most accurate results. For a c the inclined coil is in most general use. Most a-c meters will indicate as correctly on a c as on a c, but not as accurately as an instrument of the d'Arsonval type (Fig 4).

Voltmeter resembles an ammeter and in reality measures current, but its electrical circuit has a high resistance connected in series with it, to limit the current to a reasonable value. Since, in accordance with Ohm's law, with a

stant resistance the current is proportional to the potential across the cir-, the scale deflection will indicate volts. The resistance must be non-in-tive, and must not vary with temperature. When the resistance coil is rate from voltmeter the coil is called an multiplier.

e dynamometer type voltmeter is to be preferred for a c, and a potential transformer be used instead of a multiplier if required to measure a voltage higher than the range e voltmeter proper. ELECTROSTATIC VOLTMETER, a special instrument for measur-ery high voltages, utilizes the force exerted between two charged bodies. A moving is connected to one side of the circuit, a fixed vane to the other. As the high poten-charges these vanes, a force is exerted between them causing the movable vane to e. This instrument is used for potentials greater than 10 000 volts, either a c or d c.

Wattmeter is used on both a-c and d-c circuits for measuring the true or active er in watts; *EI* in d-c circuits, *EI cos* ϕ in a-c circuits. In d-c circuits a meter and an ammeter may be used to measure power, the product of the s and amperes giving true power, but in an a-c circuit this is not true. The tmeter has a potential coil connected in parallel with the load (like a volt-er), and a current coil connected in series with the load (like an ammeter). e needle shows negative deflection, the terminals of one coil or other must be rsed. Range of the wattmeter must be selected with reference to the volt current capacity of its coils. A "multiplier" may be used in the potential and a current transformer in the circuit of the current coil.

Watt-hour meter measures energy by recording watt-seconds. Coils are arranged to a motor, which causes a disk to revolve at a velocity proportional to the power. A ter registers number of revolutions of the disk, and this number represents energy. t-hour meters for a-c circuits are constructed differently from those for d-c. (Art 11.)

Power-factor meter determines the phase angle (ϕ) between voltage and ent of an a-c circuit. Since in practice the power factor is the more impor-t, the scale is graduated in *cos* ϕ. Instrument is constructed like a wattmeter ing 2 coils, one for potential and one for current.

Frequency meter indicates the frequency in electrical cycles per second of the circuit age. The two common types are the vibrating reed and the induction. They are nected to the line-like voltmeters.

Recording meters are often used in power stations to provide a continuous record of age, current or power. A pen, attached to the indicating element, rests on a strip isk of paper, and draws a line as the paper moves by clock work.

5. Direct-current Generators

Application. Direct-current (recently officially named continuous current) aratus is used for short transmission distances. For long distances the a-c em (Art 7) is preferable, because the transformer (Art 13) permits trans-sion at very high voltages. However, since the d-c motor is more convenient more easily controlled than the a-c motor, the d-c system is used whenever sible. It is often found advisable to generate and transmit by means of a c, ch is then converted to d c at the place where the motors are located. Thus, it generating stations produce a c, though many of the motors supplied by e stations use d c provided by synchronous converters.

Fundamental principle of a dynamo is the production of e m f (Art 2) in one or more luctors by the motion of these conductors in a magnetic field. In most machines the f is alternating; first positive, as conductor passes a north pole, then negative, as it es a south pole. For use as a d-c machine a commutator must be provided to rectify age and current. The commutator is the distinguishing feature between d-c and machines. Small machines are usually of the bipolar type, with a more or less en-ed frame of cylindrical shape. Large machines are multipolar; that is, hav-e number of inwardly projecting radial pole pieces. Commutating pole or INTF

machines have small auxiliary poles placed alternately with respect to the main poles and excited by a few turns in series with the load. Effect of these poles is to improve commutation of the machine. Machines are divided generally into belt-driven and direct-connected, the former having the higher speed.

Shunt machine, either generator or motor, is one in which the entire excitation is derived from a circuit of many turns and high resistance, connected in shunt or multiple with the armature circuit (Art 6, Fig 8). The characteristic of a shunt generator is poor regulation; that is, voltage decreases as load increases, and hand regulation of a rheostat in the field is necessary to provide steady voltage.

Compound-wound machine has on each field pole, in addition to its shunt winding, a few turns of thick wire which carry the load current and are known as series winding (Fig 5, 6). This causes excitation to increase as load increases, and tends to keep the terminal voltage constant or even to increase it. If the field windings are proportioned to cause a higher voltage at full load than at no load the machine is over-compounded. A flat-compounded machine has the same voltage at full load as at no load, and a compounded machine has a lower voltage at full than at load. A compound-wound machine may be connected either in short shunt (Fig 5), which is usual practice, or in long shunt (Fig 6), in which the field winding is connected from outside of the series field to outside of the armature.

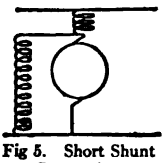

Fig 5. Short Shunt Connections

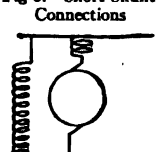

Fig 6. Long Shunt Connections

Constant potential vs constant current. In constant-potential type an endeavor is made to maintain a constant potential across the load. For particular purposes machines sometimes have the field connected in series with the armature, and with a special regulating device for giving constant current irrespective of load. These machines were formerly much used in arc lighting, but are not now built.

Installation. In installing and erecting a d-c machine, certain features must receive careful attention, so that the machine shall operate properly and not deteriorate too rapidly. The most important considerations are: (*a*) For large machines the base is bolted to the foundation in accordance with the drawings. (*b*) Bearings are lined up, cleaned, and oiled. (*c*) Field coils are tested for open circuit and wrong connections. Test is made with a compass for correct polarity. For a self-excited generator there is one particular connection of the field to the armature for each direction of rotation. (*d*) Armature must be properly centered so that the air gap is correct at all points. Gap is measured by taper wedges. (*e*) Magnet frame is bolted to base. (*f*) Commutator is smooth and polished. Use sand paper, never emery paper, to polish commutator. Brushes are properly and accurately spaced around the commutator, sandpapered and fitted to its curvature, and their pressure adjusted to the correct value, usually 1.5 to 2 lb per sq in of contact surface. (*h*) Field connections are adjusted for correct direction of rotation and substantial connections made. (*i*) Machine must be protected from moisture during shipment; if it be damp it must be dried out by heat before being subjected to a voltage.

Operation. In starting a single generator it may be necessary to CREATE THE FIELD by exciting the shunt field separately for a moment to set up residual magnetism. To cause the machine to PICK UP, or generate voltage by self-excitation, the rheostat connected in series with the shunt field must be cut out or short-circuited. If total resistance of shunt-field circuit exceeds a certain critical value the machine will not "pick up," however much time is allowed

ırallel operation. For economical operation of a power station there must number of machines, whose aggregate capacity equals the maximum de- d on the station. As the demand varies the number of machines in oper- ı is adjusted so that those running are operating at a load near their rating, therefore at good efficiency. To operate SHUNT GENERATORS in parallel t is, feeding the same bus-bars), it is only necessary to adjust all to the : polarity and voltage, connect them to the bus-bars, and adjust division ad by strengthening the field of the underloaded machine if voltage of the bars is low, or weakening the field of the overloaded machine if voltage is . To operate COMPOUND GENERATORS in parallel there must be an equalizer ıection, making a common connection on all the machines at the point 'een the armature and the series field (Fig 7). The equalizer divides the current in proper proportion between the series fields of the different gen- ›rs, preventing the machines from acting as series generators or differential ›rs, which would cause short-circuits. For successful operation of compound hines in multiple all those connected to set of bus-bars must have same amount ompounding, and same voltage at no . The compounding curves of machines t be investigated before they are oper- in parallel. With unlike curves, one hine may be overloaded while another ıderloaded, unless the field current of of them is adjusted.

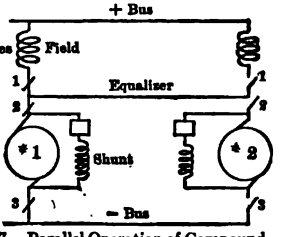

Fig 7. Parallel Operation of Compound-wound Generators

a machine is to be connected in parallel ı those already in operation it must have ıer polarity and voltage, the equalizer ıit must be made, and the switches are :d in the order 1, 2, 3, as in Fig 7. With any other order the effect is the : as having no equalizer. In shutting down one machine, switch No 3 must pened first; then No 2 and No 1.

[anagement. See Art 6.

esting. D-c machines are tested for regulation, commutation, and heating, ıubjecting them to a load, but their efficiency is best determined by the rate loss method, for which the machine need not be run under load. Cus- ary commercial tests are:

) **Resistance measurements** are made on armature winding, shunt field, and series , at known temp, before the machine is run and again after the heat run (*d*). Re- nce of a lap or multiple winding is found by measuring between two diametrically site points on commutator. If this resistance be R', then the actual armature re- nce is $R_a = 4\,R' \div p^2$, where p = number of poles on machine. Resistance of a series- ıd armature is found by measuring between two commutator segments separated distance equal to periphery of commutator divided by number of poles. Resistance ıe brush contact can not be accurately measured by any simple means, as its value is ted by value of the current, speed of commutator and pressure of brushes. An pted method is to assume a total loss of 2 volts in all brushes.

) **Core loss and friction (stray power).** Machine is run as motor without load, current being held at proper value and the voltage applied to armature adjusted to desired speed. Input to armature is measured; subtracting from this the calculated of armature circuit, the net value of input = core loss + friction.

) **Load runs.** Machine is run and the excitation adjusted to give proper voltage at ıad. Load is then added and terminal voltage noted. If E_0 = voltage at no load E = voltage at full load, the regulation is $(E_0 - E) \div E$. Brushes must be set in ıer position for commutation, which is judged by observing action of brushes at no l, full load, and 150% load.

(*d*) **Heat runs** are made by operating at full load until the temps of the various p that can be noted during operation become constant. The greater the machine's capac the longer is the testing time required. Heat runs are sometimes made at 1.25 or times rated load for 2 hr. Heat runs may be made either by the DEAD-LOAD METH which a resistance load such as a water rheostat is connected to the terminals and rated load power is required to drive the machine; or by the Hopkinson or PUMPING METHOD, in which 2 machines of similar characteristics are run in multiple, one acting a generator to supply electrical power to the other as motor, which in turn drives the by a belt or equivalent mechanical connection. For this test a LOSS SUPPLY is requi which may consist of a source of either electrical or mechanical power. The power quired is from 10 to 20% of the rating of one machine. During a heat run, thermo readings are taken at stated periods, showing temp of frame, field-coils, bearings, and surrounding air. After the run thermometers are placed on various parts of the ma the bulbs being protected from radiation by small cotton pads, and the temps are noted armature core surface, ventilating ducts and winding, commutator surface, pole-t field-coils, bearings, frame, and room. Resistance of the electrical circuits sho measured, and average temp of the copper calculated from: $t_1 = (R_1 \div R_0)(239+t_0) - 2$ where R_1 and R_0 are the hot and cold resistances, and t_1 and t_0 are the hot and cold temp

(*e*) **Compounding test.** To adjust the current in series field so that a compound wound generator will give specified voltages at no load and full load, the machine is operated at no load and current in shunt field adjusted to give desired no-load voltage. Load is then put on, and it will usually be found that the terminal voltage is too great. Strips of German silver or other resistance metal are then connected across the series field terminals, until by shunting current from the series field the machine voltage is reduced to desired value. This "series-field shunt" is then insulated, and made up permanent form. Before making the no-load adjustment, it is advisable to overexcite the shunt field for a moment to overcome hysteresis.

(*f*) **Insulation tests.** After the heat run the insulation is tested, first by measuring its resistance and then by applying a high-potential test. INSULATION RESISTANCE is found by connecting one terminal of a 500-volt d-c circuit to the windings through a 500 voltmeter, and connecting the other terminal of the 500-volt circuit to the machine frame. If voltmeter resistance is R_v and the deflection during above connection is x, then insulation resistance in ohms is: $R = R_v(500 - x) \div x$. The value of R should be approximately one megohm (1 000 000 ohms) for each 1 000 volts of rated potential of the machine. HIGH-POTENTIAL test is made by applying an alternating high potential between each winding and the frame of the machine for 1 min, in accordance with specifications adopted by Am Inst Elec Engrs. This test is usually made only at the factory and should be under supervision of an experienced person.

6. Direct-current Motors and Motor-generator Sets

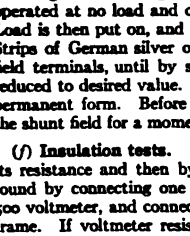

Fig 8. Shunt-Motor Connection

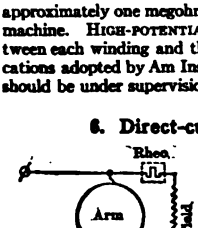

Fig 9. Series-Motor Connection

Shunt motor (Fig 8) has only one exciting winding which is connected across armature terminals, and in parallel or shunt with the armature. Field winding consists of a large number of turns of fine wire on each pole, and all poles are usually connected in series in the circuit. Field current depends upon line voltage and resistance of field winding. Resistance of field winding is made high, so that the field current will be between 1% (large motors) and 5% (small motors) of the full-load current of motor. The characteristic of the shunt motor is a fairly constant speed for all reasonable load values.

Series motor (Fig 9) has only one exciting winding which is connected in series with the armature, and so the current flows through both field and armature. Field winding consists of a few turns of thick wire on each pole, the windings on all poles being connected in series. Field current depends upon the load; larger

heavy load and small with light. Resistance of field winding is made low, iat loss of voltage and power in that circuit will be small. Characteristics series motor are: a speed varying with every change in load, high speed at load, and low speed at heavy load. Efficiency is high throughout a wide e of speed. Speed will be dangerously high at no load; thus a series motor t always be connected rigidly to its load. Since torque is high at low speeds, motor is especially adapted to work requiring frequent starting.

ompound motor. Usual form is the cumulative motor, each pole of h has both series and shunt winding, wound and connected for mutual tance in producing the magnetic field. It is a combination of shunt and s motor, designed to give the good starting qualities of the series motor and void danger of excessive speed at light loads. DIFFERENTIAL MOTOR has osed shunt and series winding; not much used and not recommended.

iclosed vs open type referring to the mechanical housing of the motor. N TYPE has all parts freely exposed to the air and is therefore well ventilated. nded to be used indoors or in protected places. INCLOSED TYPE is for use xposed locations, where there is liability of dampness and dirt. Special ns must be provided to circulate air inside the machine, but even then an osed motor is larger and more expensive than an open motor of same capacity. itive capacities in output of open, semi-inclosed and totally inclosed motors, shown by Table 6. Inclosed motor generally weighs about 15% more than pen motor of same capacity, notwithstanding that it is allowed by comcial convention to operate at 15° C higher temp.

Table 6. Data of Typical Commercial Motors

Type	Output, h p	Temp rise, deg C	Weight, lb	Speed, r p m
en	10.0	40	970	700
mi-inclosed	8.0	40	970	700
tally inclosed	5.75	55	970	775

ating. Motors are rated on basis of their continuous or their intermittent icity. CONTINUOUS RATING is the output in h p (or kw) which a motor will continuously with a maximum temp rise (measured by thermometer above ounding air) not exceeding 40, 50, or 70° C in field or armature, depending n character of insulating material (Art 1). INTERMITTENT RATING is the ut which the motor will give for 1 hr (starting at room temp), with a maxm rise in temp above surrounding air not exceeding the above values (Standzation Rules of Am Inst Elec Engs, 1914, Art 1).

oltage and current. Usual values of voltage for d-c motors are: 110–125 small units on lighting circuits; 220–250 for motors in factories, shops, and es, on power mains or on outside mains of a 3-wire system; 500–600 for ral railway work; 1 200–2 400 for heavy railway work. Current in amperes ired for any motor is: I = (output in h p × 746) ÷ (effic × voltage). Usual iencies of motors of different sizes are given in Table 7.

pplications of motors. Chief applications of d-c motors: SHUNT MOTOR, ing shafting, machine tools, blowers, reciprocating pumps, motor-generators; IES MOTOR, R R, and all transportation work, hoists, cranes; COMPOUND OR, elevators, hoists, and machinery that is stopped and started frequently.

peed characteristics. Shunt motor is always used when constant speed is

may have same speed at full load as at no load, but in this case the mot quires special attention in starting and is subject to bad commutation at loads. At full load the speed of any well-designed shunt motor may be incre to equal the no-load speed, by putting resistance into the field circuit. Vari speed motors are of the series type; they decrease in speed as load incre every change in load causing change in speed. Multispeed motors are of type, and usually have commutating poles so that they may operate with dif strengths of field without suffering from bad commutation. They may be trolled by varying the field resistance, or the voltage impressed upon the arma By increasing resistance in series with the field of a shunt motor speed is incr due to weakening of the field. If the motor has commutating poles, to assure commutation, speed may be varied in ratio of 1 to 2, or even 1 to 3 in small Motor speed is stable with this mode of control and efficiency is good.

Potential control. By means of several generators and several wires various dif voltages are available. Thus, with one main generator giving 240 volts and 3 sm ones giving 40, 80, and 120 volts, combinations may be made giving 40, 80, 120, 160, and 240 volts. By connecting the armature terminals to these voltages, the motor run at speeds proportional to the voltages. The shunt field is left continuously connec to one circuit, usually the maximum voltage circuit. A shunt motor with normal ex tion will be stable at each speed; that is, will operate at fairly constant speed irrespec of load. Efficiency will be good at all speeds. A number of wires are needed to make different voltages available at the places where the motors are located.

Adjustable-speed motors. By connecting a rheostat in series with a shunt armature, the voltage impressed upon the armature will be reduced by an amount portional to the current, and speed will thereby be reduced. The speed is unst changing with every change of load, and efficiency is poor.

Starting box (rheostat) is always employed in starting d-c motors, to red the voltage impressed on the armature when not running at a speed high en to generate the proper counter e m f. Fig shows usual connections of a starting bo the line and motor.

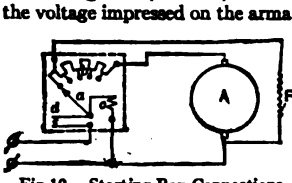

Fig 10. Starting Box Connections for Shunt Motor

Starting box contains: (*a*) means of opera closing the circuit supplying current to the m including the field current; (*b*) set of resis steps in series with motor armature, and a of short-circuiting this resistance step by (*c*) a magnet coil connected across the mot minals to open the circuit if impressed fails (low-voltage release); (*d*) a magnet coil carrying main current to actuate a and open main circuit, if current exceeds a specified value (overload release).

Specifications. In calling for bids for d-c motors it is customary to spe kind of service and load, method of drive, voltage, horse-power, speed whether open, semi-inclosed or inclosed, series, shunt, or compound-wound shunt-wound, whether shunt field rheostat is to be supplied; if compound-wo whether cumulative or differential; dimensions of pulley and shaft extens whether rails or base are required; whether starting box is to be supplied if so, the style; temp rise for continuous full load; temp rise for 25% over efficiency at 25, 50, 75, 100, 125, and 150% load; starting torque requir necessity for withstanding moisture; regulation; percentage of variation speed between no load and full load, with field resistance constant; variation speed at full load obtainable by variation of field rheostat.

Installation. (See Art 5.)

Operation. All motors should be frequently inspected and following point noted: (*a*) Bearings filled with proper amount of oil; (*b*) brushes securely held

roper position; (*c*) brushes fit properly; (*d*) commutator smooth: look high mica," or projection of the insulation above the bars; (*e*) air gap (*f*) commutator not worn in grooves.

oubles. Following troubles that may occur in operating d-c motors, and causes, are stated by Crocker and Wheeler: (*a*) Sparking at commu-. Causes: armature carries too much load, brushes improperly spaced ot in proper position, rough commutator, poor brush contact, internal short pen circuit, field too weak, unequal strength of poles, vibration. (*b*) Heat- of commutator and brushes. Causes: sparking, bearing trouble, bad con- ions, brush friction too great. (*c*) Heating of armature. Causes: overload, rnal short circuit, moisture or ground, reversed coil. (*d*) Heating of Cause: internal short circuit. (*e*) Heating of bearings. Causes: ings dry or dirty, shaft out of true, bearings out of line, thrust due to belt, lanced magnetic pull. (*f*) Noise. Causes: armature not balanced, hes dry or not set at proper angle, armature strikes. (*g*) Speed too low. ses: wrong voltage, overload, armature strikes, bearing too tight. (*h*) Speed high. Causes: wrong voltage, field too weak. (*i*) Motor stops, or fails art. Causes: overload, open circuit, wrong connection.

sts. A motor is usually tested for resistance of insulation and of windings, heat run, power, regulation and commutation. Regulation test consists in measuring speed at ad and at full load. Other tests are the same as made on d-c generators (Art 5).

nstants. Efficiency of any particular size of electrical machine may vary widely rding to its design. For weight and cost, see Art 19.

Table 7. Average or Usual Constants for D-C Machines

w rating	1	5	10	20	50	100	200	500
ficiency at full load	0.80	0.84	0.86	0.88	0.90	0.91	0.92	0.93
v per min	2 000	1 100	850	680	650	600	450	350

Motor-generator set is a combination of motor and generator having sepa- fields and armatures, but mounted on same shaft with common base and rings. The two machines may both be for d c, both for a c, or one for each, ccordance with the use to which the plant is to be put.

rincipal applications are:

alancers. Two similar d-c machines mounted on the shaft, and connected in series ss the mains of a 250-volt circuit. From the common connection a third wire is ght out, thus giving a 3-wire system for 125-volt lamps on each leg, and for 250-volt ps on the outside main. With compound machines the regulation on the 125-volt uits is good.

oosters. To raise the voltage on a particular feeder a series booster is used, consist- of a shunt motor driving a series generator, the latter being connected in series with ply and feeder. The set runs at constant speed, and the voltage increases with the ent to the load. Voltage at full load is from 10 to 20% of the rated voltage of the uit. The combination may be designed to neutralize loss in voltage due to drop in feeder.

Multiple-voltage systems. Motor-generator sets are used to give the fractional ages required for these systems. Each set consists of 2 or 3 machines operating as a ancer; that is, each may be a motor at one moment and a generator at the next, depend- upon which circuit is supplying the load.

Ward-Leonard system. For regulating the speed of a motor a special gen- tor may be provided, which, being driven by its own motor, forms a motor- erator set. By varying the field strength of the generator any voltage may generated, from 0 to full rated voltage. If this generator supplies only the

armature of the motor the speed of which is to be regulated, its speed may controlled from o to full speed by merely varying the small current flowing the field of the special generator. Main supply circuit furnishes current the motor of the set, field of the generator, and field of the controlled motor.

Ilgner sets. Where a motor must start and accelerate a heavy load frequently, as in mine hoists and rolling mills, the motor is advantageously supplied from a special set, consisting of a motor (shunt or induction) driving a special generator, with a heavy flywheel forming part of the set. The set motor may have poor speed regulation. As the accelerating motor starts, it draws a heavy current from the generator, causing the speed of the set to drop and the flywheel to give up a considerable amount of stored energy. This energy supplies the peak demands, and when the peak load period has passed the set speeds up gradually and stores more energy in the flywheel. This combination is expensive, but is used where conditions limit the maximum demand which may be made on the electrical supply system. (See Sec 16, Art 9.)

7. Alternating-current Circuits

Sine wave. Every generator for d c as well as for a c has induced in its armature windings an alternating voltage. The commutator of the d-c machine rectifies this, giving direct or continuous voltage. Since an a-c machine has no commutator, this voltage is brought to the load in its alternating form by sliprings.

In designing machines every endeavor is made to obtain an e m f which follows a sine law: $e = E_m \sin \theta$, in which e is the instantaneous value, E_m the maximum value and θ gives the phase time, or scissa at which the instantaneous value is specified. All calculations of a-c circuits are based on assumption that voltage and current follow a sine law.

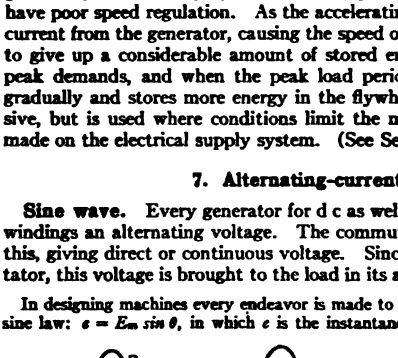

Fig 11. Alternating-current Voltage and Power, Rectangular Coordinates

Frequency. The series of values from a to c (Fig 11) constitutes a cycle or period. Time in seconds required for one cycle is the periodic time T, and $1 \div T$ (number of cycles per sec) is the frequency. In commercial practice frequencies of 25, 50, and 60 cycles per sec are used, the first for general power, the latter for lighting purposes. If θ is expressed in radians then $\theta = 2\pi ft$, and $\theta = 2\pi f \times t$. The term phase θ is a conventional means of expressing a given instant of time t. A cycle may be divided into 360°, and θ may be the abscissa expressed in degrees.

Effective, virtual, or root mean square value of an a c is equal to that value of a d c which would produce the same heating effect or average power loss in a resistance RI^2. If current follows a sine law, the effective value is equal to maximum value divided by $\sqrt{2}$. Effective value of e m f is that which, when multiplied by the effective value of current in a simple resistance, will give the true power in watts. It is also equal to maximum value divided by $\sqrt{2}$. Effective values of current and voltage are the values shown by all instruments, and are the only ones used in practical engineering. (See Sec 16, Art 9.)

Inductive reactance, inductive circuit. Any circuit in which the presence of a current produces a magnetic flux is an inductive circuit, the quantity of inductance depending upon the number of turns and the quantity of flux produced by one ampere. When an

ws in an inductive circuit the current lags behind the impressed e m f, and the relation en voltage and current in such a circuit is $E = 2\pi fLI$, where E = effective value of f = frequency in cycles per sec, L = inductance in henries, I = effective value of nt. $X_L = 2\pi fL$ is the inductive reactance in ohms. $E = X_L I$ in a circuit having in- nce only, and the current will lag behind the voltage by one-quarter of a period.

pacity reactance, anti-inductive circuit. If an alternating e m f is impressed upon uit having capacity only, the current which flows precedes or leads the e m f by 90°, ts value is $I = 2\pi fCE$, where C is the capacity in farads and the other quantities s in preceding paragraph. $X_c = 1 \div 2\pi fC$, called capacity reactance, is expressed ms and $E = IX_c$.

›wer and power factor. In an a-c circuit containing inductance or capac- as well as resistance, the product of effective volts and effective amperes does not give true power, because the current will be out of phase with the ge; that is, the maximum value of current will occur either later than or e the maximum value of voltage. Therefore EI is the volt-amperes or arent power." Ratio of true power P to apparent power is the power r. It may be proved that the power factor is equal to the cosine of the of phase difference between the voltage and current as shown by equation: r factor = $\cos\phi = P \div EI$, where ϕ is the time differ- in phase between voltage and current, expressed in lar measure.

11 shows an alternating voltage E and an a c I differing ase by an angle ϕ, which means that their maximum or their alues occur at a difference in time of $(\phi \div 360)$ T sec, where the periodic time of one cycle. Fig 12 is a vector repre- tion of these quantities, and conventionally I is said to lag d E by an angle ϕ. $E\cos\phi$ is the component of the voltage ase with the current, and is called the "active component." useful or heat power in watts is $P = EI\cos\phi$. $E\sin\phi$ is omponent of the voltage out of phase with the current, and led the "reactive component." $Q = EI\sin\phi$ is the reactive power, as it reacts on the ssed forces without producing useful work or heat. Total volt-amperes or apparent r is $EI = \sqrt{P^2 + Q^2}$.

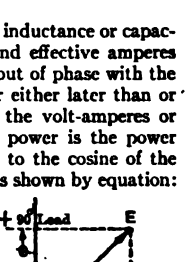

Fig 12. Vector Diagram of Alternating-current Voltage

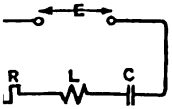
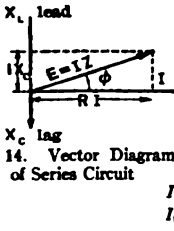
lculations. A corollary of the law of conservation of energy is that the sum of all rue (heat) power consumed in a circuit is equal to the input of true power, $P_0 = P_1 + P_2 + P_3$. The sum of all the reactive power consumed in a circuit is equal to the input of reactive power, $Q_0 = Q_1 + Q_2 +$ etc, and $E_0 I_0 = \sqrt{P_0^2 + Q_0^2}$.



3. Series A-c Circuit, h Resistance Induc- ce and Capacity

Kirchoff's laws for a-c circuits. FIRST LAW (for series circuits) (Fig 13 and 14): The sum of all active components of voltage ($E\cos\phi = IR$) in a closed circuit is equal to zero, and the sum of all reactive components ($E\sin\phi = IX$) is equal to zero. Hence,

$$E_0\cos\phi_0 = E_1\cos\phi_1 + E_2\cos\phi_2 + \text{etc}$$
$$E_0\sin\phi_0 = E_1\sin\phi_1 \pm E_2\sin\phi_2 + \text{etc}$$
$$E_0^2 = (E_0\cos\phi_0)^2 + (E_0\sin\phi_0)^2$$



14. Vector Diagram of Series Circuit

Reactive component of voltage in an inductance is positive; that in a capacity is negative. SECOND LAW (for multiple circuits) (Fig 15 and 16): The sum of all active components of current ($I\cos\phi = ER \div Z^2$) meeting at a point is equal to zero, and the sum of all the reactive components ($I\sin\phi = EX \div Z^2$) is equal to zero.

$$I_0\cos\phi_0 = I_1\cos\phi_1 + I_2\cos\phi_2$$
$$I_0\sin\phi_0 = I_1\sin\phi_1 + I_2\sin\phi_2 - I_3\sin\phi_3$$
$$I_0^2 = (I_0\cos\phi_0)^2 + (I_0\sin\phi_0)^2$$

eactive component of current in an inductance is negative; in a capacity, p

Ohm's law for series a-c circuits (Fig 13). In a circuit having resistance R, inductive reactance X_L, and capacity reactance X_c in series, the impedance in ohms is $Z = \sqrt{R^2 + (X_L - X_c)^2}$, the current $I = E \div Z$, and the power factor $\cos\phi = R \div Z$. Voltage across the resistance RI (Fig 14) is in phase with the current. Voltage across the reactance IX_L is 90° ahead of the current, and the voltage across the capacity IX_c is 90° behind the current. These combine geometrically to give $E = IZ = \sqrt{(RI)^2 + (X_L I - X_c I)^2}$, which differs in phase from I by the angle ϕ, the $\cos$ of which $= R \div Z$, and $\tan = (X_L - X_c) \div R$.

Multiple circuits (Fig 15, 16). In multiple circuits having resistance and reactance in various branches:

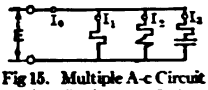


Fig 15. Multiple A-c Circuit with Resistance Inductance and Capacity

Conductance	$G_0 = R_1 \div Z_1^2 + R_2 \div Z_2^2 + R_3 \div Z_3^2 + \cdots$
Susceptance	$B_0 = X_L \div Z_2^2 + X_c \div Z_3^2$
Admittance	$Y_0 = 1 \div Z_0 = \sqrt{G_0^2 + B_0^2}$
Current	$I_0 = E_0 Y_0, \quad \cos\phi_0 = G_0 \div Y_0$

The negative sign is used to denote a lagging current in inductance in multiple circuits.

Resonance. If an inductance and capacity are connected in series, the voltages across them are opposite in sign; if equal in magnitude their resultant or difference is zero. This is resonance in series circuits. If an inductance and capacity are connected in parallel the two currents will oppose each other; if the currents are equal a large current may flow in each, but the resultant current in the supply circuit is zero or very small. This is resonance in multiple circuits. The phenomenon is utilized to regulate long transmission lines. The line has inductance, while near the load a synchronous motor is installed, which can act like a large condenser. By adjusting the excitation of the latter its capacity effect is varied until it neutralizes the line inductance, and it is possible to obtain a higher voltage at the load than is given by the generating station.

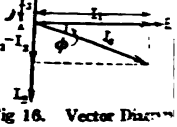

Fig 16. Vector Diagram of Multiple Circuit

Polyphase circuits. The single-phase a-c system, while simpler to calculate and best for lighting purposes, is not satisfactory for general transmission of power purposes. This is because: (*a*) a polyphase machine, whether generator or motor, weighs and costs less than a single-phase machine; (*b*) single-phase motors will not start from rest without complicated auxiliary devices; (*c*) in transmission work the 3-phase system requires only 75% as much copper for given power and voltage as the single or 2-phase systems. Therefore most commercial installations use 2-phase, while the great majority use 3-phase.

Two-phase system (sometimes called quarter-phase) consists of 2 circuits, which are electrically independent and come from independent circuits in the generator. Voltage of each circuit is the same, and it is endeavored to maintain same current in each. This is called balanced conditions. Generally 4 wires are required, though sometimes 3 wires are used; the latter arrangement is undesirable as it causes poor regulation. The wiring connections of 2-phase circuit are simple, as each phase is treated as an independent single-phase circuit.

Three-phase system saves 25% of the copper required for transmission line, as compared with any other commercial system, and is in general use. Theoretically, it consists of 3 independent circuits in which the 3 e m f's differ in phase by a period, or 120 electrical degrees. Since the currents in the 3 circuits combine to neutralize each other the 3 return wires are not necessary and the out-going current may use a wire returns by the other two without interference with regulation is, therefore, common in practice machinery to connect the 3 windings inside the machine so that only 3 conductors are brought out from the machine. There are two methods of making this connection. Fig 17 shows a Y-connected generator lea...

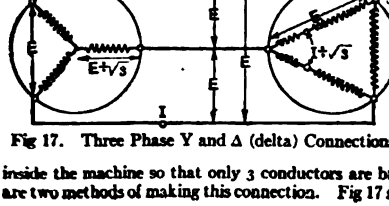

Fig 17. Three Phase Y and Δ (delta) Connections

base line, at the other end of which is a delta (Δ) connected motor. The different ges in this system have definite ratios as follows: Let E be the voltage between any es of the transmission line, and I the current in each line: Generator voltage per $= E \div \sqrt{3}$. Line voltage (neutral) $= E \div \sqrt{3}$. Motor voltage per phase $= E$. ator current per phase $= I$. Motor current per phase $= I \div \sqrt{3}$.
oice of Y or delta-connections is a matter of convenience, except for some exceptional of apparatus. To the operator it makes no difference which connection is used, and t it is impossible to tell without having the design drawings.

yphase transformations. There may be systems of 5, 6, or any number of phases, he 1, 2, and 3-phase systems are the only ones used for transmission. Some ma- have 6-phase windings, but these are always supplied by 3-phase transmission lines ethods of converting from one polyphase system to another see Art 13.

8. Alternating-current Generators

nchronous generators. Field structure consists of a number of poles, ed by coils carrying a d c. The relative motion of armature conductors ield structure generates the voltage. Frequency of the voltage depends tly upon number of field poles and rev per min of revolving part. Revolv- eld generators make more effective use of material than those with re- ng armatures, and are more easily insulated for high voltages. Most gener- of greater capacity than 300 kw are of the revolving-field type. Advantages: regulation, high efficiency, and satisfactory operation in parallel. Most ators built at present are separately excited, because voltage regulators ow available which are simpler and more reliable than the self-excited ines formerly in use. INDUCTOR GENERATORS are a special form of syn- ous machine having a revolving-field structure consisting of a spider with projecting poles, and one coil of d c which excites all poles.

duction generators are constructed like induction motors. The magnetic is of the rotating polyphase type, produced by a c in same windings as the current. An induction generator must always be connected to a synchro- generator, from which it must receive its excitation. Only a minority of nits of a station may be of the induction type. Advantage: less violent s in case of short circuits.

nnections (single, two, and three-phase). Single-phase generator is ly about 30% heavier and more costly than a polyphase of same rating. and three-phase generators of same capacity and voltage are practically me dimensions, weight, and cost. By changing the internal armature ctions any polyphase machine may be reconnected to a 3, 2 or single-phase ine. As transmission by 3-phase currents is more economical of copper by 2-phase or single-phase currents, all transmission lines are 3-phase; , the 3-phase generator is preferable.

ltage. Alternators are now built for voltages up to 13 000 and 15 000 en lines, either single or polyphase. For higher voltage, owing to extra f insulation and danger of damage, it is cheaper to install transformers a lower voltage alternator.

equency depends upon speed of rotation and number of poles. If the ve speed of revolving part is given in rev per min, the frequency is $f = (\text{r p m}$ les) ÷ 120. Formerly it was found more economical to run alternators gh speeds. Hence frequencies as high as 133 and 125 cycles per sec were mary; but, as systems increased in size and complexity, high frequencies d electrical difficulties. Usual frequencies are now 60, 50, 40, and 25 cycles c, of which 25 and 60 are standard in U S. In Europe 50 cycle id of 60. Recently there has been an attempt to have 15 or

standardized for railway work. Frequency of 25 cycles is preferable for re long transmission lines, because of the lower inductive voltage drop; and where there is much synchronous machinery (synchronous motors and rot converters), as these are more stable and better adapted to parallel operatio low frequencies. Higher frequency (60 cycles in U S, 50 in Europe) is pref able for electric lighting, as the light is steadier; it is also preferable where tr transformers are used, as these are cheaper and more efficient at high freque

Single phase. In a single-phase generator the voltage per phase is the sa as voltage between lines, and the current per phase is the same as current p line. The product of voltage and current gives the volt-ampere rating.

Two-phase or quarter-phase. Each phase supplies half the rating; th the voltage and current per phase in the machine are the same as the volt and current per phase of the line. The current is

$$I = \text{Power output in watts} \div 2\,E\phi$$

Three-phase machines may be either Y or delta-connected. In both cas the relation between output, current in each line, and voltage between lines the same:

$$I = \text{Power output in watts} \div \sqrt{3}\,E\phi$$

where I = amperes in each line; E = volts between lines; ϕ = load power-fact

Tests. Principal commercial tests on a-c generators are: resistance, cold and h friction; saturation and coreloss; synchronous impedance and load loss; heat run a insulation. Friction, coreloss, and saturation tests are made during one run; synchron impedance and load loss during another. For testing, the generator is driven by a m motor of about 1/10 the capacity of the generator. Synchronous impedance is use calculate regulation of the generator; results of the other tests give the efficiency. Lo are friction, coreloss, excitation, armature I^2R or copper loss, and load loss. Efficienc the output divided by the output plus all losses at that output. Armature I^2R and l loss vary as the square of the load; other losses are approximately constant. Heat r may be made by operating the generator under normal load conditions, or by a co promise method in which the generator supplies current to a synchronous motor w runs free and is under-excited, the current being wattless or reactive. Temp of wind after the heat run is determined by comparing their resistance at that time with th resistance when machine was at a known (room) temp.

Usual efficiencies at full load for different sizes of generator are given Table 8. These values are merely indications and vary with frequency, volta speed, power-factor, etc. A 60-cycle low-voltage machine will probably ha better efficiency than a machine of same rati for 25 cycles or high voltage.

Table 8. Usual Efficiencies

Rating, *kw*	Efficiency, %
100	91
500	94
1 000	95
2 000	96
3 000	96.5
5 000	97
10 000	97.2

Regulation of a generator is defined as the ra of the difference in terminal voltage at no load a at full load to the voltage at full load, the field e tation being kept constant at full load value the speed being constant. Expressed as a per ce age, the regulation is $100\,(V_0 - V) \div V$, where terminal voltage at full load and V_0 is term voltage at no load, with excitation for full loa Usual value, 5 to 15%.

Operation. In the operation of an a-c generator several factors are sidered: EXCITATION. A-c generators of the synchronous type (that in m general use), require d c to excite their field windings; usually obtained fr an exciter, which is driven by a separate engine, or by an electric motor, or f the generator itself by belt or other mechanical connection. Usual potent for field circuit is 125 volts, though some machines are designed for excitatio

volts. Since most machines have revolving fields, the d c is led into the coils by collector rings on the main shaft. In series with exciter and field uit a rheostat is connected, to vary the current in field coils, and thereby excitation and voltage of the generator. Usual power for excitation is from :o 2.5% of rating. Before STARTING A GENERATOR its bearings are inspected, ned, and oiled. Machine is then brought up to speed, and bearings again ected to see that oil rings are running properly. Exciter or excitation cir- is then put in readiness, and the rheostat in alternator-field circuit adjusted naximum resistance. Before exciting the field the armature insulation must horoughly dry; otherwise, the armature is short-circuited through an am- :r, and run for several hours at a partial excitation to give about rated current ie short-circuited armature. When insulation is thoroughly dry the short uit is removed and the excitation adjusted to give rated voltage in armature iinals at correct speed. To stop the machine, load is first removed by open- :he circuit breaker; then the field rheostat is turned to maximum resistance, also the rheostat in the exciter field if there is an individual exciter. Field uit is then opened.

ıralleling of generators. Before connecting a generator to the bus bars (to which or more other generators are connected), following conditions must be satisfied: requency of generator must be the same as that of bus bars; (*b*) frequency of gen- ır, and therefore its speed, be constant for an appre- e interval of time; (*c*) volt- of generator must be the : as that of bus bars; (*d*) rator and bus-bar voltage : be in phase. two machines have not the : frequency, or if frequency t constant, a condition will occur intermittently in which the voltages are 180° apart, e machines are in series on a short circuit, and a dangerous current will flow. If volt- are not equal, a large wattless current may flow, and if they are not in phase, a large r current will flow, causing a mechanical shock.

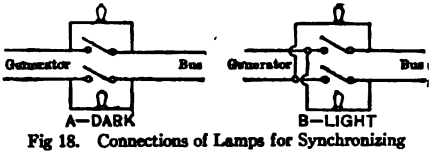

Fig 18. Connections of Lamps for Synchronizing

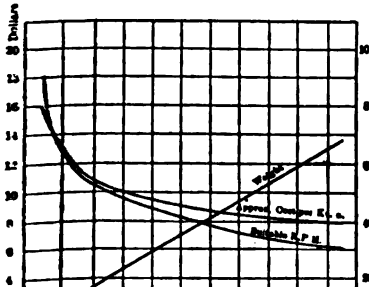
Two methods are used for determining when these conditions are favorable for connecting the machines together without disturbance; that is, for indicating when the machines are in SYNCHRONISM. For synchronizing with lamps, the connections as in Fig 18a are such that the lamps remain dark when above conditions are satisfied; with connections as in Fig 18b, they will remain bright. If the frequencies are wrong, the lamps will flicker (the slower the flicker the nearer the frequencies). If voltages are wrong, lamps will glow slightly but steadily. SYNCHRONOSCOPE is an instrument which indicates the relative frequencies and phases of a alternators; usually installed on switch board of a station, if a number of generators are used.



19. Cost, Weight, and Suitable Speed of Water-wheel Driven A-c Generators

ost and weight. Generators vary widely in their specific weights and ---- is, weight and cost per *kva* rating; but they may be divided into cla:

which these characteristics are fairly definite. Conditions affecting specific weight are: method of rating, speed, frequency, voltage, and size. Method of rating is fundamental. For comparison, rating is taken as the output in kw which each machine will give continuously with a temp rise not exceeding 45° C. On this basis, specific weight decreases as the speed, frequency or capacity increases, and it increases with increase of voltage. A-c generators are divided into 3 classes according to their speeds and purposes: high speed, as turbine-driven generators; medium speed, as belt-driven and water-wheel driven; slow speed, or engine-driven. Fig 19 shows approximate weights, costs per kva and suitable speeds, for medium-speed, 60-cycle, 2 400-volt polyphase machines. Weight and cost of 25-cycle generators are from 10 to 20% greater than for 60-cycle. These data are suitable only for preliminary estimates. Costs particularly are subject to large variations due to changes in commercial conditions from year to year. For final estimates exact dimensions and quotations must be obtained from manufacturers (see Art 19).

9. Synchronous Motors

Operation. Any alternator will operate as a motor. If two synchronous alternators are connected in parallel to bus bars supplying a load, and the driving power is removed from one prime mover, the alternator connected to this prime mover will continue to run at same speed, taking power from the other alternator and driving its own prime mover or other apparatus coupled to it; this alternator thus acts as a motor. Speed of such a motor depends solely upon the speed of the generator or generators supplying electric energy to it; it is therefore said to run in "synchronism" with source of supply and is called a synchronous motor. The speed of a synchronous motor having p poles and supplied with current of a frequency of f cycles per sec, is: r p m = $120f \div p$. If load on the motor increases, speed will not decrease, unless load reaches a value so excessive that the maximum output or "pull-out torque" is reached; then the motor will drop out of step and come to rest, while the current takes will increase to short-circuit value and torque will decrease to a negligible value. Difference in construction between an alternator and a synchronous motor is that the latter has, in the face of the field poles, a squirrel-cage winding, intended to give good starting torque and prevent "hunting" while running. HUNTING defines the occasional undesirable action of synchronous machines, of varying in speed, current, and voltage, at a frequency observable in meters. If excessive a short circuit results (see Specifications below). A standard 2 300-volt generator will operate satisfactorily as a motor at 2 080 volts, and as these are the natural values of the generated and delivered voltages, this characteristic of the synchronous motor accords well with customary distribution practice. A standard generator may have a squirrel-cage winding added to its poles and become a good synchronous motor.

Number of phases. Synchronous motors may be single, 2, or 3-phase. The single-phase motor is not self-starting, and has a considerably lower efficiency than the polyphase. It is also more liable to hunt and be unstable, and is therefore far less desirable than a polyphase motor. The 2 and 3-phase motors are very similar in all their characteristics.

Terminal voltage. Since synchronous motors are usually built with a revolving field and a stationary armature, the armature winding can be insulated for voltages as high as 13 000, thus often obviating need of transformers.

Relations of voltage and current. Relations between line voltage and phase voltage are the same as in a-c generators (Art 8). Current in each line of a 3-phase motor $I = \frac{746\,P}{\sqrt{3}\,\epsilon E \cos\phi}$, where P = output, h p; E = voltage between lines; ϵ = efficiency;

ed load; $\cos\phi$ = power factor (may be unity). Usual values for efficiency are the same as for a-c generators.

vantages of synchronous as contrasted with induction motors: higher effi-y, higher power factor, controllability of power factor with constant speed, voltage, lower cost. DISADVANTAGES: need of an exciter, will not start load, possibility of hunting.

plications. To transform from a c to d c, or from one kind of a c to ier differing in frequency, potential, or phase relation, motor-generator sets, sting of a synchronous motor direct connected to one or more generators, ften employed (Art 6). The potential of the secondary or distribution t is thus made independent of the variation in potential of the primary it supplying power to the motor. In certain cases it is desired to take power a 25-cycle circuit and supply power at 60 cycles for lighting purposes. a synchronous motor-generator set would be used; often called a "fre-y changer." In some applications of electric drive by induction motor ynchronous motor is installed to make it take leading current, in order to alize the lagging current taken by the induction motors. This effect is ıced by over-exciting the fields of the synchronous motor. The motor be used to drive any machinery not requiring much starting torque. Such tor is a "rotary phase modifier" or "rotary condenser " (see below).

its of synchronous motors. The first four tests of an a-c generator (Art 8) apply synchronous motors.

ıse characteristics, or V-curves at no load, full load, and any other specified load. ine is operated as motor with specified load kept constant throughout the run. ge and frequency impressed upon the motor are also kept constant. Current in the s varied from minimum at which motor will operate to the maximum (from 0.25 to rmal), and the variation in current input to armature noted. Readings are taken d, volts armature, amperes armature, and amperes field. A curve is plotted with es armature as ordinates, and amperes field or ampere turns per pole in field as sas. This gives the characteristic V-curves. At point of minimum current input ch load the power factor is unity. At lesser values of field current the armature it lags and power factor is poorer; at greater values the armature current leads.

rting tests. A low voltage is impressed on the armature and gradually increased the motor starts. Field circuit is open in two or more places, and a high-potential ltmeter is connected across one section to determine the voltage induced in field by the rotating magnetic flux. Test is repeated for several different initial positions revolving part, and a record made of time required for machine to reach synchro-Synchronous speed is attained when the induced voltage in the field becomes zero. ngs are taken of volts armature, amperes armature, initial position, maximum volts time to reach synchronism.

ıtallation and operation. Precautions to be taken in installation are the as for a-c generators (Art 8). Direct current must be provided for excita-If a synchronous motor is operated on a polyphase system having unbalanced ges, it will take unequal currents in the different lines and tend to balance the ges. But these unequal currents increase the heating for a given load.

ırting. Provision must be made for reduced voltage when starting the r, either by means of taps on the transformers or by a starting compensator 13). Large motors require 2 steps in starting, ½ and ¾ of normal voltage. motors will start with 1 step at ½ voltage. Field circuit is opened by eld "break-up" switch, and a voltage applied to the armature. When rmature current has decreased from its large starting value to a reasonable the voltage is increased, step by step. When motor reaches maximum the field is excited and the motor pulls into exact synchronism. Field nt is then adjusted until the condition of minimum armature cu

found, or until the power-factor indicator records a unity power factor. Lo may then be applied.

If a synchronous motor is to be started several times a day, a special starting m is desirable. This brings the synchronous motor up to a speed a little above synchron which is then effected as in a-c generators. Such a starting motor would require o about 30% of the full-load current of the large motor, and therefore have little effect the regulation of the system and not cause disturbance to lights and other motors on system. It usually requires less than one min to bring a motor up to speed.

Specifications. Synchronous motors are rated in same manner as synch nous generators, and same heating limits and specifications apply (Art 8). It customary to specify the value of current taken by the motor in starting with load other than the friction of its own bearings; or its own friction plus that the machine to which it is connected, in case it is part of a motor-generator s It is sometimes stated in specifications that the motor will not hunt, provid the total resistance drop between generator and motor is less than some speci value (10 or 15%).

Dimensions, weight, and costs. These are approximately the same as f synchronous generators of the same *kva* rating (Art 8, 19).

10. Induction Motors

Principles. Induction motor is a machine having distributed windings. E those of the armature of a d-c machine, on both stationary and revolving mem bers. One winding, the primary, receives polyphase currents from the supp circuit and thereby sets up a rotating magnetic field. This field cuts the co ductors of the secondary winding, induces currents in it, and thereby drags along with the field. The action is reversible; either member may be the pri mary, provided it is connected to the line. That member which remains stati ary, whether it be primary or secondary, is called the stator; the other, th rotor. In U S the stator is usually primary.

Synchronous speed. Speed of rotation of the magnetic flux is called th synchronous speed. At light loads the rotor speed is nearly equal to the syn chronous speed. If f is the frequency of the current, and p the number of pa of motor windings, the synchronous speed is: rev per min $= 120 f \div p$.

Slip. At any appreciable load the rotor speed is less than the synchron speed. Difference between the actual rotor speed N_1, and synchronous speed is "slip." It may be expressed as a percentage or a fraction: $S = (N - N_1) \div N$

Methods of rating. Amer Inst of Elec Engs recommends that the rat of an induction motor shall be the h p which it will deliver continuously at t shaft with a maximum rise in temp not injurious to its insulation (Art 1).

Starting and break-down torque. In addition to the ability to carry rated load without excessive heating and with reasonable values for efficien power factor, and slip, the motor should be able to start such loads as must brought up to speed, because good starting ability in an induction motor involv certain complications and expense. It is important also that the motor be able to carry momentary overloads without "breaking down," that is, gradua decreasing in speed to a standstill. To prevent this the maximum motor out put must be known and should be at least 50% greater than rated output.

Frequency and speed. Induction motors can be built for any frequency The higher frequencies are satisfactory where the load never exceeds the normal. Frequencies as low as 25 are preferable where overloads are common, or hig starting torques are required. Rotor speed of an induction motor at norm loads approaches within 5 to 10% of the synchronous speed, which is fixed b

requency of the system and the number of poles (see above). Hence, for ven frequency of supply circuit, only certain speeds are available. Thus, 5 cycles, the rev per min are: 1 500 for 2 poles; 750 for 4 poles; 500 for les; 375 for 8 poles, etc.

ase connections. Two-phase or quarter-phase motors are usually wound with inde- ent phase windings. Three-phase motors are connected in Y or delta, depending upon nience of designing engineer. In single-phase and 2-phase motors the voltage and nt per phase are the same as voltage between lines and current in line; in a Y-connected se motor, the current per phase is equal to line current, and voltage per phase is equal e voltage divided by $\sqrt{3}$; in a delta-connected 3-phase motor the current per phase is to line current divided by $\sqrt{3}$, and voltage per phase is equal to line voltage.

rrents taken by motors. Let: P_0 = output, h p; I = current in each line; e = ncy as a decimal fraction; $p = cos\,\phi$ = power factor as a decimal fraction; E = ge between lines (between one outside wire and the middle wire for 3-wire, 2-phase Then, for 2-phase: $I = 373\,P_0 \div peE$; for 3-phase: $I = 431\,P_0 \div peE$.

9. Power Factors and Efficiencies at Full Rated Load for Polyphase Motors

H p	25 cycles		60 cycles	
	Effic	Power factor	Effic	Power factor
1	0.79	0.78	0.78	0.78
5	0.85	0.88	0.82	0.88

100	0.905	0.925	0.89	0.92
200	0.91	0.925	0.905	0.92

sting. Induction motors may be given an "input-output" test (Art 5) at working from which efficiency, power-factor, slip, and maximum output may be determined; no-load excitation and a id short-circuit test, from i all characteristics may be lated. The former is sim- a stray-power test (Art 5) d-c motor, the latter to a nce measurement. No- tests require very little r, and are preferable in the of large motors, where it l be expensive to supply r and inconvenient to dis- the energy. They are ly accurate.

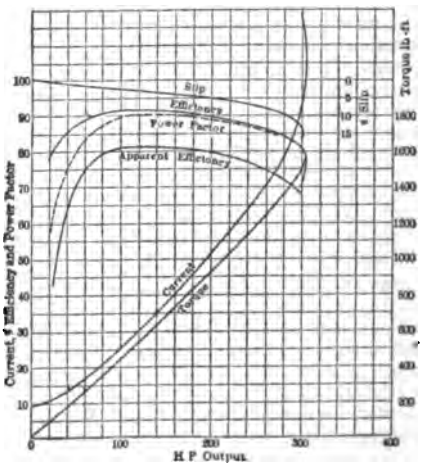

Fig 20. Characteristic Curves of a 3-Phase Induction Motor

aracteristic curves. Fig 20 examples of the usual char- stic curves of an induction . Typical break down of curves at maximum output wn at 300 h p. Power-fac- rve shows relation between rue power input and the ent power, or volt-amperes. power factor involves no er registration of the watt- meter, or cost of energy to te the motor, but does in- poor voltage regulation of the system as a whole and a larger capacity of w formers, etc. Apparent efficiency is the product of the power factor and tru

ency and is equal to output in watts divided by input in volt-amperes. Its value d
mines the actual capacity of the lines and transformer supplying the motor.

Starting. To start an induction motor without injurious heating, a resi
must be connected in the secondary circuit, or the voltage impressed up
primary must be reduced. These methods are known as RHEOSTATIC CON
and POTENTIAL CONTROL. They are also available to control the motor spe

Potential control consists in reducing and regulating the voltage impressed
primary usually by a starting compensator or auto-transformer, which provides
ratio of voltages. For this the secondary must be of higher resistance than
for the most of starting, but no changes of connection of the secondary are nec
Hence a squirrel-cage rotor winding is used, made of one bar per slot, all bars
connected at both ends to solid copper rings. To start the motor the primary
switch is thrown on the compensator, which gives a voltage of from ⅓ to ⅗ the rated v
a small motor and ½ to ½ if it is large. A small motor may be brought
speed with this voltage, but a larger one may require an intermediate step. When
speed indicated by the low, steady value of the current) it is connected
full voltage.

Rheostatic control. Better apparent torque efficiency, that is, more torque
given current, is obtained by inserting in the secondary circuit a much greater re
than can be permanently used. To do this a special starting resistance is connec
series with each of the armature windings, and a switch provided for short-circuiting
resistance either step by step or as a whole, as the motor speeds up. There are two
general methods. The first is for use only when the torque required at starting is
small, in which case the starting resistance may be small and placed within the arm
frame. The switch lever is so arranged that the resistance can be short-circuite
steps while the armature is revolving, thus obviating the need of collector rings and
connections. The second method, for large starting torque, consists of bringing the
ends of the secondary winding to collector rings. From brushes on these rings conduc
through external resistances, with steps or taps, so that the resistance can be short-circui
gradually by a controller.

Speed control. Speed of an induction motor may be controlled in 5 w
(*a*) By varying the potential applied to the primary of a motor having su
permanent resistance in the secondary. (*b*) By varying the resistance in exte
circuit of the secondary. (*c*) By so changing the internal connections of
primary winding as to change the number of poles. (*d*) By connecting two m
in "concatenation" (similar to series connection). That is, the stator of
motor is connected to the supply, rotor of first motor is connected direct
rotor of the second, and stator of second motor is treated as its secondary.
(*e*) By changing frequency of the applied voltage. Method (*b*) (rheostat
the most general and practical where more than 2 speeds are required; any s
may be obtained. Method (*c*) is best where only 1 motor is available and
2 speeds are required. Method (*d*) requires 2 motors and gives 2 sp
not as desirable as (*c*). Method (*e*) is of theoretical interest only.

Installation. Induction motors, even in large sizes, are usually self-conta
the bearings being a part of the end frame of the motor. They are either dir
connected or belted. Belt drive is the commoner, since an induction m
can be built only for a definite speed, corresponding to a certain number of
Small motors need no foundation, and are often attached to the wall or ce
the bearings and end shield being so made that they may be turned through
or 180°, for proper operation of the oil rings. Most motors must have ra
free ventilation, free from dust and dirt. For severe service, as in cement
or mines, motors are built totally inclosed ("iron-clad") and may then be ev
submerged in water. This increases both size and cost.

Operation. Small motors are designed to start merely by closing the
switch. With larger motors, if starting switch is in proper position, note

be applied to the motor, and the starting resistance gradually cut out by switch. Induction motors are very sensitive to variations in the impressed age. A decrease from 100 to 80 volts will cause the maximum output and ing torque to decrease from 100 to 64, with a roughly proportional increase eating for a given load. UNEQUAL VOLTAGES in the different phases cause ease in maximum output, and increase in heating for a given output. An alancing of 25% in voltage doubles the heating effect at full load; giving same heating as 50% overload. CARE IN STARTING. Before starting for irst time, see that the starting device is in operating condition and in proper tion, to avoid injurious heating. Wiring must be proportioned to carry the ing current without an excessive drop in voltage (see above).

ults. Some of the common faults in induction motors, with their indications and dies, are: SECONDARY OPEN-CIRCUITED. Motor will not start, and will not take a nt greater than exciting current; probably due to the starting resistance not being ected in. ONE PHASE OF SECONDARY OPEN-CIRCUITED. Motor tends to remain at synchronous speed, although the current is apparently normal. If the armature is ted, the currents in primary will be unbalanced. ONE PHASE OF PRIMARY OPEN. or will not start, and current will be unbalanced. ONE PHASE OF PRIMARY REVERSED. ents in primary will be very much unbalanced when motor is running, and starting ue will be very slight. SHORT-CIRCUITED COIL IN PRIMARY. There will be hum- when potential is applied to the motor and excessive local heating around the short- ited coil. VIBRATION due to mechanical unbalancing is chiefly noticeable at high ds, particularly in high-speed machines. If vibration is due to magnetic unbalancing, probably caused by inequality in the air gap at different portions of circumference, at different positions of armature. It may be detected by measuring the air gap taper wedges at different points around the circumference, with the armature in ral positions.

pecifications. Following memoranda (from Amer Handbook for Elec s) will assist in framing specifications: PRINCIPAL CHARACTERISTICS AND DITIONS OF SERVICE. Use to which motor is to be put; kind of load and hod of drive; voltage and number of phases; rating, horse-power; frequency speed. STYLE AND DESCRIPTION; CONSTRUCTION DETAILS. Whether to pen, semi-inclosed or inclosed; requirements regarding pulley and length of ft; whether rails are required; method of starting; compensator, external stance or internal resistance; whether motor is to be run at speeds other than speed; whether starting devices are to be supplied. PERFORMANCE AND TS. Final temp rise at full-rated load; temp rise in 2 hr at 25% overload applied ediately after full-load run; efficiency at 25, 50, 75, 100, 125, and 150% load; ting torque with full-load rent, ft-lb; high-potential s of insulation; require- nts as to effect of moisture n insulation.

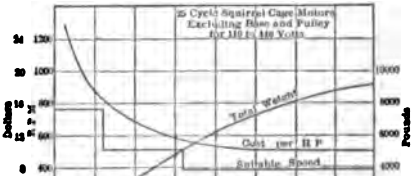

Fig 21. Weight, Cost, and Suitable Speed of a Line of 25-Cycle Induction Motors

Weight and cost of induc- n motors vary with type of nature winding and character nechanical frame and hous- ; also with speed, frequency, l voltage. Curves in Fig 21 l 22 indicate weights and ts of a line of 25-cycle and cycle motors respectively, ring squirrel-cage rotors (the mplest and least expensive type), and with simplest form of mechanical fr cy therefore represent minimum values (see also Art 19).

Single-phase motors may be of either induction or commutator type. I
DUCTION TYPE is the commoner, as its constant-speed characteristic is more ge
erally appropriate than the variable speed of the usual commutator a-c m
A 2 or 3-phase induction motor may be operated as a single-phase machine
it is once up to speed; but it has lower efficiency and power factor, and small
maximum output than it would have as a polyphase motor. Slip, for a giv
output, is less in a single than in a polyphase motor. Because of the poo
operating characteristics, and especially the smaller maximum output or ma
imum torque, the motor m
be rated at lower capacity w
run single phase. A sing
phase motor having same fr
and wt of iron and copper a
polyphase motor will rate

phase motor. STARTING.
single-phase induction mo

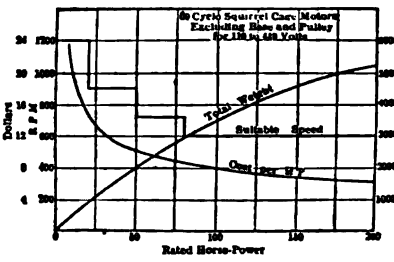

Fig 22. Weight, Cost, and Suitable Speed of a Line of 60-Cycle Induction Motors

has no torque at standstill, and must be started by some such means as a ph
splitting device. It may be started in either direction, and immediately dev
a slight torque, which increases with speed. When the torque reaches a valu
overcome friction and inertia the starting device may be disconnected, and th
motor will continue to accelerate to its proper speed. A small motor may
started without auxiliary aid by giving the armature a spin by hand. It will th
accelerate if there is no load. Some small motors are designed with a loose pull
which is clutched at a certain speed by a centrifugal governor. These motors ma
be provided with "shading coils," or with a small phase-splitting device, to gi
them enough starting torque to overcome their own friction. Large motor
are sometimes started by a phase-splitting device consisting of a resistance a
reactance connected to 2 windings of the motor. This gives an unbalan
3-phase voltage on the motor which produces a starting torque. Or, a commu
tor on the rotor may be used, making it possible to operate as a repulsion m
(see below) having good starting qualities. After reaching considerable spe
the brushes are removed and the secondary windings are short-circuited

Commutator type. The several types of a-c commutator motors designed to oper
on single-phase circuits differ chiefly in their electrical connections. They may be div
into series motors and repulsion motors. Both have an armature wound like that
d-c motor and a commutator. SERIES A-C MOTOR is connected like a d-c series mo
and has the same general characteristics. Principal difference is that the a-c mot
an extra winding placed in the face of the poles and connected in series with armat
and field. This winding improves the power factor. Limiting feature of most a-c c
mutator motors is sparking at the brushes, which is much worse than in d-c mot
REPULSION motor has a stationary structure or field (primary) with a completely dist
uted winding like that of an induction motor. The winding may be for any voltag
The armature or secondary is like that of a d-c commutator motor. The commutat
brushes are short-circuited upon themselves, and are placed at a small angle away fr
the neutral. This motor acts like a combination of transformer and series motor, ha
the variable speed, high torque, and runaway characteristics of the series motor. It
started by applying a reduced potential to the primary, and is reversed by moving the
brushes or by reversing the current in one particular portion of the primary winding known
as the exciting turns. REPULSION-INDUCTION TYPE of motor is made in small sizes as

: machinery requiring good starting torque. It is a repulsion motor with extra hes on the commutator, the brushes being connected across a portion of the primary. gives a constant speed characteristic like a shunt motor, and a good power factor.

11. Synchronous Converters

nce it is more economical to transmit electrical energy in the form of a c more convenient to utilize it in the form of d c, some means of converting trical energy from one form to the other is desirable. For this purpose hronous converters and motor-generator sets (Art 6) are available.

onstruction. A synchronous converter, also called "rotary converter," milar to a d-c generator, in which certain commutator segments, or the con- ors leading from them, are connected to 2, 3, 4, or 6 collector rings. When movable member rotates, the voltage between any 2 rings is alternating. 1 a machine may be operated as an a-c generator, or as a "double-current" rator giving a c from its collector rings and d c from its commutator. If rings are connected to an a-c source, the machine will run as a synchronous or, and d c may be obtained from the commutator brushes; that is, the ma- e with but one set of windings acts simultaneously as an a-c motor and a generator. It therefore has the friction, core-loss, and excitation loss of one hine instead of two; and since the motor and generator currents flow in e winding, and in opposite directions, they more or less balance each other, the armature RI^2 loss is much less than in either a motor or generator alone.

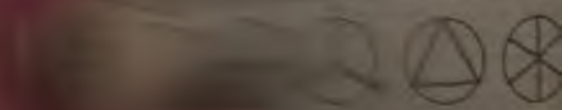
onverter *versus* motor generator. A converter is much more efficient, hs and costs less than a motor-generator set of same capacity, and occupies space. But, since only one winding is used, there is a definite relation veen the voltages of the a-c and d-c terminals. Maximum value of the mating wave bears a definite relation to the direct e m f (see below). The rerter must therefore be supplied with a voltage of the same order as the ct voltage, which requires transformers if a high-voltage transmission line ed to supply the converter. EFFICIENCY of a converter approximates 93%, of the transformers, 97%; the efficiency of the combination is therefore it 90%. Efficiency of a synchronous motor is about 93% and of a d-c rator, 92%; hence the combination motor-generator set has an efficiency 5.5%. If the supply voltage is greater than 13 000 volts, transformers will be needed for the motor-generator set, the net efficiency being then 83%.

ctifier differs from a converter, in that the latter gives a direct e m f of constant and rm value, and the former a pulsating unidirectional voltage and current. In the erter the energy is stored for an instant in the form of magnetism; in the rectifier : is no magnetic field and no storage of energy. A rectifier will not work on an in- ive d-c circuit, but a converter will.

pplication of converters. The commonest application of synchronous rerters is in electric railway work. Nearly all motors for electric traction of d-c series type, operating at 500 to 600 volts. For this service the energy ansmitted over long distances, requiring a high-voltage a-c transmission and converters to link the d-c distribution with the a-c transmission.

ases and rings. SINGLE-PHASE CONVERTER has 2 collector rings, each connected to windings by as many equally spaced taps as there are pairs of poles. The taps for rings alternate at equal spaces. A single-phase converter is therefore a 2-ring erter. THREE-PHASE CONVERTER has 3 rings and 3 equally spaced taps (one for each for every pair of poles. A 4-phase or quarter-phase converter has 4 rings and 4 and a SIX-PHASE CONVERTER has 6 rings and 6 taps per pair of poles.

unt and compound-wound converters. A converter may be shunt or compound d, depending upon the service. Series winding is intended to make the com



nsformers to supply converters. The transformer secondaries must give a tage which is a definite fraction of the direct voltage desired (Table 10).

Starting. A converter may be started by either of the methods described synchronous motors, or it may be speeded up as a shunt motor, and then chronized with the a-c supply circuit like an alternator (Art 8). All conters are supplied with a "field break-up switch," which opens the field circuit several places to avoid the strain of the high potential induced in field windgs during starting, and to reverse direction of field current after the machine ıp to speed, in order to reverse the polarity if necessary. This is usually a ible-throw switch with several poles. For normal operation it is thrown rn to "running" position. To change the polarity it is thrown up to "rese" position and left closed only for a moment; then it is returned to nning" position. SPEED-LIMITING DEVICE. In case a converter should be connected from the main a-c supply circuit, and still remain connected to the circuit, it would tend to operate as a d-c motor, and its speed might become ngerously high. To avoid this a centrifugal governor is placed on the shaft l arranged to open the main d-c switches of the converter.

12. Electric Power Plants (See also Sec 16)

Location of an electrical power plant is governed by: Form of power; disnution of load; cost of ground; possibility of good foundations; room for ension; convenience of coal, and of water supply for evaporation and consing; limitation of voltage used.

Form of power, whether steam or water, is usually definitely determined by al conditions. Choice between steam, gas, or oil depends chiefly on relative t of fuel and of maintenance of an oil or gas engine. If steam is to be used, choice between turbines and reciprocating engines is governed largely by of units; in large sizes the steam turbine costs less per h p and is cheaper operate, while in small sizes the reciprocating engine is more economical. designing a power plant and selecting the number and size of units, it is portant that the total capacity be sufficient to carry the maximum load with rgin, and that it be divided into units of a size to carry average load economily. Each unit is usually capable of carrying 25 or 50% overload for 2 hr. ere should be at least 4 units in a large plant, and nothing is gained by having re than 8 units. A sufficient number of exciters are necessary to carry the ık load, with one exciter to spare. Transformers are commonly arranged in ups, one group for each generator. In hydro-electric plants it is often visable to install 1 or 2 steam-driven units and boilers, to serve if water supply uld fail (see also Sec 16).

Alternating vs direct current. Choice depends upon length of transmission and value of energy. For utilizing all the energy within a short distance the generating station d c is preferable, because d-c motors (particularly in all sizes) are more convenient, easier to control, and are available in greater riety of form and characteristics than a-c motors. But the voltage obtaine from a d-c generator is limited by the commutator to about 600; and, for nsmission to a considerable distance by d c, the quantity of copper becomes hibitive; hence a c is used, and with the a-c transformer the transmission potential is independent of the voltage at either generators or motors. The iding line between the best fields for d-c and for a-c plant is not clear cut, l can be determined only by careful calculation and comparison of costs. ne installations use a-c generators and a c for transmission, but these are ıverted into d c in sub-stations near the point of utilization, and at a di m the generating station. When the sub-station cost is less than th

ence between the cost of the copper requisite for d c and for a c, the a-c system with sub-station is preferable. If the a-c system be chosen, 3-phase generators are advisable, as 3-phase transmission requires 25% less copper than 2 phase or single phase, and there is no advantage in the 2 phase over the 3 phase. If the power plant is for a varied service, including lights as well as motors, the frequency should be 60 cycles, because incandescent lights operated at 60 cycles are satisfactory, while at 25 cycles the flickering is harmful to the eyes. Transformers for 60 cycles are considerably cheaper than those for 25 cycles. But if the system is primarily for transmission, and at the place of utilization comparatively large synchronous motors or converters, then 25-cycle frequency is better, as this type of machine sometimes gives trouble when operated at 60 cycles.

Voltage. The most convenient and widely used voltage for a local power plant is the 220–240 volt 3-wire system, in which two 110-volt generators are connected in series, or a 220-volt generator and a balancer set provide the two voltages. In this case the electric lights and small motors are connected to the 110 volts from the neutral to either of the outside wires, while all the larger motors receive 220 volts from the 2 outside wires, thereby saving in copper. If 110 volts were used, either an excessive amount of copper would be required, or the voltage on the lamps would vary enough to cause dissatisfaction. For a number of large motors, 500 volts is generally used, but the lighting problem then becomes difficult, as the lamps must be connected in groups of 4 in series, and if any one of the 4 burns out, all in that group go dark. 500 volts is also undesirable in damp places, as in a mine, because there is danger of an unpleasant shock, particularly to horses or mules. The 220-volt, 3-wire system is therefore best, if d c be used. For the 3-phase a-c system the distribution circuits are best run at 220 volts between lines, giving a good voltage for motors, while the lights may be distributed on the 3 phases by transformers giving 110–125 volts on the low potential side. Lowest standard voltage for transmission is 2 200, which will take care of reasonable loads within a radius of 1 or 2 miles from the power station, stepdown transformers being used to supply the different sections of the area.

Arrangement. It is common practice to divide the power station, if steam or gas driven, into two parts, separated by a fireproof, dustproof wall. On one side are the boilers or gas producers; on the other, the prime movers, generators, and all electrical apparatus. In the simplest form the boilers are set in a single row along one side of this wall, and the generating units along the other side, the piping being so arranged that any engine may be supplied from any boiler. If transformers are used, they are generally placed in the room with the generators, but on opposite side and on the lowest level, the switchboard being in a gallery above. Cables from generators to switchboard are run underneath the floor and running up the side of the wall.

Switchboards are of 2 kinds: DIRECT CONTROL, in which case the current is carried by bus bars immediately behind the switchboard panel, the opening and closing of switches in this circuit being effected directly by the operator; and REMOTE CONTROL, in which the current is carried by conductors placed in brick compartments in the basement, and the connections are made by electrically operated switches controlled by a small relay circuit coming from control switches on a benchboard above. If potential is 2 200 or less, and power is less than 5 000 kw, direct control is satisfactory and feasible, but for greater voltage or power the remote control system is preferable.

Switchboard is divided into a number of units, each known as a panel. There are generator panels, exciter panels, and feeder panels, and at one end of the switchboard is a voltmeter; also, in an a-c station, a synchroscope is placed on a swinging bracket which may be distinctly seen from any part of the switchboard. A circuit-breaker is a switch which opens the circuit when current is excessive; operated by hand or automatically by

current itself. While the make-up and arrangement of the different panels may vary tly according to individual ideas, the essentials are common to all, as follows. D-C ERATOR PANEL, 2-wire system: 1 circuit-breaker at top of board, 1 ammeter, 1 hand-el for rheostat, 1 field rheostat back of board, 1 single-pole field switch, 1 triple-pole a switch (or 1 double and 1 single-pole) for the equalizer, 1 4-point voltmeter receptacle. FEEDER PANEL 2-wire system: 1 single-pole circuit breaker, 1 ammeter, 1 double or ugle-pole main swtiches, 1 4-point voltmeter receptacle, 1 watt-hr meter. A-C GEN-TOR PANEL, 3 phase: 3 ammeters, 1 3-phase wattmeter, 1 field ammeter, 1 double-pole switch, 1 handwheel for rheostat, 1 synchronizing receptacle, 1 potential receptacle, phase oil switch, 3 disconnecting switches, 2 current transformers, 1 potential trans-er, 1 voltmeter for group, 1 synchronizer for group. A-C FEEDER OR OUTGOING LINE EL, 3-phase: 3 ammeters, 1 3-phase oil switch, 3 disconnecting switches, 1 polyphase -hr meter, 3 current transformers. A VOLTAGE REGULATOR may be used, requiring adependent panel.

osts. See Art 19.

13. Electric Transmission

ypes. Transmission may be in form of single-phase, 2-phase or 3-phase or as d c. Single-phase and d-c systems require 2 wires; 3-phase, 3 wires; ase, 4 wires. For given voltage between wires the relative weights of copper Single-phase and 2-phase, 100; 3-phase, 75; d c, 50. Because of the ted voltage at which d c is obtainable, it is not applicable to long distances. le-phase system is used where the object is lighting only, on account of its le connections. For important transmission problems the 3-phase system ld be chosen. Respecting the transmission line only, 25 cycles is preferable o cycles, due to the lower inductive and capacity effect; but, for ordinary smission problems, the higher frequency is preferable, because of the lower of 60-cycle transformers.

ine drop is the difference between voltage at generating station and at the l. It is usually expressed as a percentage of the delivered voltage, and t transmission lines are designed for 10% drop when transmitting full or d load power. In general, the weight of copper required varies inversely he line drop allowed. This is not strictly true in a-c systems, but is exact in systems, and the relation may be written: $W = 125\,PD^2 + KE^2$, where wt of copper, lb; P = power delivered, watts; D = distance one way, in sands of ft; K = ratio of power lost in line to power delivered; E = voltage vered.

an a-c system the inductive reactance must be considered, as well as the resistance. stance for a certain length of given size of wire is obtained from a wire table, and is ated for the given distance. Inductance in henries per mile for one wire of a trans-ion system is given by: $L = 74 \times 10^{-6} \times \log_{10}(2D \div d)$, where D = distance between s, and d = diam of wire, both in inches. Reactance in ohms is $x = 2\pi fL$, where f e frequency. In a single-phase transmission the total resistance and reactance are e the above values. In a 2-phase circuit, the resistance and reactance per phase are e the above values. In a 3-phase circuit, the resistance and reactance per line or per ase are used, and these are the values given by the above formulas.

ine regulation depends upon: line resistance and reactance, the current, and power or of the load. It may be calculated by: $E_0^2 = (pE_1 + IR)^2 + (IX \pm qE_1)^2$, where voltage at generating end; I = load current per line; $p = cos\,\phi$ and $q = sin\,\phi$ at load; qE_1 is negative for anti-inductive load; E_1 = voltage at receiving end; X = re-nce of line; R = resistance of line. For single-phase, E_1 is the voltage at the load, and nd X are taken as the sum of outgoing and return circuits. For 2-phase, E_1 is the age per phase at the load, and I is the current per phase in a 2-phase system (Art 7); nd X being taken for the complete circuit of one phase, outgoing and return. For ase, E_1 is the voltage to neutral at the load = 0.58 × voltage between lines; I is the ent per line, or Y current; R and X are taken for one line, one way. This gives E_0, voltage to neutral at generating station. Voltage between lines is then 1.73 E_0.

Size of wire for an a-c transmission. Select first a wire which gives an allowable resistance drop (IR = 5 to 10%), and then find loss in voltage [E_0 (generator) $- E_1$ (load)] due to combined effect of R and X. If loss be too great, select a larger wire and try again. To obtain a solution in one calculation is too complicated a problem except for experts. Remember that the impedance drop in the line (IZ) is usually much greater than the difference between generator and load voltage due to vector relations. Usual voltages for transmission wires are: 2 200, 6 600, 13 000, 19 000, and 33 000 volts between lines, whether single, 2 or 3-phase. A rough rule for choice of voltage is to allow 1 000 volts for each mile of distance between generating station and load. Usual sizes of wire are from No 4 to No 0000 B & S gage in solid conductors and larger sizes in stranded conductors (Table 4). Smaller wire than No 4 has insufficient mechanical strength. Wires larger than No 0000, if solid, would be too stiff, and would break from the repeated bending to which they are subjected.

Stranded conductor. Gage number or rating of a stranded conductor is that of a solid conductor having same cross-section of metal. Resistance and weight of a stranded conductor are greater for a given length than of a equivalent solid conductor, due to the twisted path (and hence greater length) of the individual wires. Actual length of path of the current is increased by about 7%. In spacing the 2 wires of a transmission line it is usual to allow about 1 ft for every 10 000 volts.

Transformer, commonly called static transformer, is used to transform a system of a given voltage to a higher or lower voltage. Single-phase transformer consists of 2 electrical circuits, usually of a large number of turns, interlinked with a common magnetic circuit of iron. Since the power is approx the same in both windings, the currents are inversely proportional to the voltages. Polyphase transformer is essentially two or more single-phase transformers, made into a single piece of apparatus, and so designed that at least part of the magnetic circuit is common to all the phases. A 3-phase transformer has 3 high-tension and 3 low-tension windings, arranged on an iron core (Fig 24, 25). The winding by which energy enters the transformer is the PRIMARY; that by which it leaves, the SECONDARY. Since either winding may be connected to the source of energy, these terms are not definite unless the manner of connection is also stated. HIGH-TENSION WINDING and LOW-TENSION WINDING are used to distinguish the two windings, the high-tension being the one with the greater number of turns. When the high-tension winding is connected to the source of supply, it is a STEP-DOWN TRANSFORMER; when the low-tension winding is so connected, it is a STEP-UP TRANSFORMER.

Classification of transformers. (A) according to operating characteristics. CONSTANT-POTENTIAL transformers are intended to give an approx constant potential on the secondary side; CONSTANT CURRENT, to give an approx constant current on the secondary for arc lamps. Both are designed to operate on a constant-potential supply circuit. SERIES TRANSFORMERS are connected in series with the main circuit and receive the line current in the primary. The secondary circuit includes only a meter and the secondary current will be inversely proportional to the transformer ratio. They usually supply low-reading ammeters and wattmeters from circuits carrying very heavy currents. AUTO-TRANSFORMERS OR COMPENSATORS, sometimes called single-circuit transformers, consist of one electric circuit interlinked with a magnetic circuit and a tap brought out from some part of the winding. As the voltage between this tap and either terminal of the circuit is a fraction of the total, a fractional voltage may be secured. Windings on each side

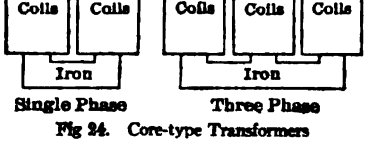


Fig 24. Core-type Transformers

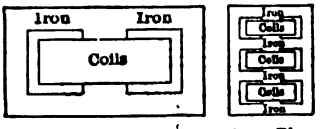
tap are usually proportioned to the current to be carried. Auto-transformers are ble where the ratio of voltages approximates unity, as they then require much less than regular transformers. POTENTIAL REGULATORS are transformers in which the e of one member may be varied from zero to a fixed maximum, either by changing the on of the magnetic flux or by changing the phase of the e m f of the secondary with t to that of the primary.

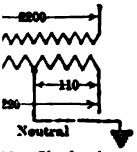
according to construction. There are two methods of arranging the electric and tic circuits of transformers, the corresponding construction being called "core-type" shell-type." CORE-TYPE transformer (Fig 24) has a single magnetic circuit inter- with 2 electric circuits, each electric circuit containing primary and secondary coils. est adapted to small sizes or high volt- nd to oil cooling, and is the commoner. -phase core-type is a combination of 3 -phase transformers into one, to save ial and space. SHELL-TYPE (Fig 25) magnetic circuits in parallel, interlinked electric circuit containing primary and dary. Best for air cooling and large its. Three-phase shell-type is a con- tion of 3 transformers into one.



Single Phase Three Phase

Fig 25. Shell-type Transformers

according to method of cooling. As a transformer is a very compact piece of appa- the problem of carrying away the heat is important. NATURALLY-COOLED type has ecial means of cooling, but relies upon ordinary circulation of air. Only used in small sizes, as for meters. In the OIL-COOLED, the core and windings are submerged letely in a tank of oil, and are subdivided by ducts so that oil may circulate and act heat from internal parts. The heat is carried to surface of tank containing the former, and thence dissipates into the surrounding air. Tank must be specially ed, with deep corrugations or projecting vanes or tubes, to provide large air-cooling ces. In the AIR-BLAST type there are passages through which air is forced by a r. WATER-COOLED transformer resembles the oil-cooled type, but a coil of pipe ing running water is submerged in the oil. Transformers artificially cooled by oil are used when the size is too great for the self-cooling oil type and no water is available. Oil circulates through external coils or tanks, to afford greater cooling surface.



16. Single-phase, Three-wire

Transformer connections commonly used in lighting and power service are: SINGLE-PHASE SYSTEM with 3-wire secondary (Fig 26) is standard practice in residence lighting with a-c system, the neutral wire being grounded on the low- tension side, the primary side not being grounded. Lamps or motors operating at 110 volts are connected between the ral and either side. Maximum potential between any secondary and ground o volts, but if either outside wire becomes grounded a short-circuit occurs hat half of the transformer. TWO-PHASE, or quarter-phase 4-wire system. standard is essentially 2 independent single- e systems, which are usually electrically pendent throughout. TWO-PHASE 3-wire em is occasionally used for distribution of er in small systems. Return wire is common oth circuits. There may be a slight saving pper, but the chances of unbalanced voltage bad regulation, especially with an inductive , render it objectionable. THREE-PHASE Y DELTA CONNECTIONS (Fig 27, 28). Trans- ation in a 3-phase system, with 3 single- e transformers or one 3-phase transformer, ng 3 primary coils and 3 secondary coils, is accomplished by connecting the ary either in Y or in delta, and the secondary either in Y or in delta. owing relations exist between voltage per transformer winding and v

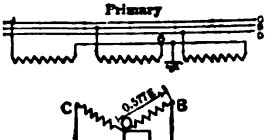


Fig 27. Three-phase Y

between lines, current in transformer windings, and current in lines. Pow the 3 transformers in any case is $3 \times 0.58 \times EI = 1.73\ EI$. THREE-PHASE

Connection	Volts between lines	Volts per winding	Current per line	Current pe winding
Y	E	$0.58E$	I	I
Delta (Δ)	E	E	I	$0.58I$

DELTA, or V-connection, saves expense by omitting one transformer from t delta connection. Is recommended only for low voltages, as 2 300. Regulati

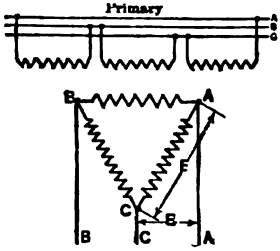

Fig 28. Three-phase Delta

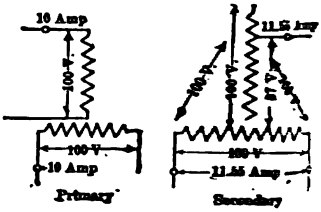

Fig 29. Two-phase to Three-phase

and efficiency are poor, as one phase of the load receives power from 2 tra formers in series. Aggregate capacity of the transformers should be 15% grea than the load. TWO-PHASE TO 3-PHASE (Fig 29). Scott, or T-connection, co sists of 2 transformers which, on the 2-phase side, are connected in norm 2-phase manner. On the 3-phase side one transformer has a tap at the midd point, the other a tap giving 87% of full-transformer voltage. Fig 29 sho method of connecting, and the currents in primary and secondary with balan loads. Total transformer capacity must be 15% greater than the load.

Efficiency is equal to the power output divided by output plus coreless p total copper loss, and is very high. "All-day efficiency" is equal to the en output for a day divided by the input; with short periods of load it is low, bec coreless goes on when there is no load. If is the load in watts for h hr per day, A the coreless, and B the copper loss, the all-da efficiency is $100\ kP \div (kP + 24\ A + kB$ percentage.

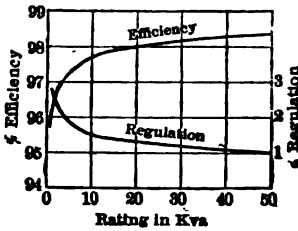

Fig 30. Efficiency and Regulation of a Line of Transformers

Regulation is $(E_0 - E) \div E$, where E_0 secondary voltage at no load and E = ondary voltage at full load. It should from 1 to 4% for load of 100% power fac and is poorer for inductive loads. Fig shows efficiency and regulation at full lo of a line of 60-cycle lighting transformer for 2 300 volts.

Installation. Transformers require no special foundations, but merely pro vision to carry their dead weight. They must be in a dry place, unless of the totally enclosed "subway" type. They are frequently placed on poles. They must be thoroughly cooled.

Cost and weight. (See Art 19.)

station is a building containing an equipment for transforming or converting the of transmission line into a convenient form for use in small units. Since the may be used as a c or d c, there are 2 general types of substations: a c to a c and d c. In either case the energy must be distributed to the various consuming de- t a much lower voltage than that of transmission, sometimes at a different fre- , and sometimes in an entirely different form. The substation is therefore the g point between the transmission and distribution systems. A-C SUBSTATION in it form comprises step-down transformers for lowering the voltage, and incidental ing and protective devices. There may be a group of 3 single-phase transformers, 3-phase. Single-phase transformers are preferable for moderate sizes, as they re- smaller reserve. Since the transmission system is always 3-phase, these groups e low-voltage 3-phase currents for different groups of motors, or the individual may be wired separately for lighting purposes. If transmission system is 25 cycles be necessary to install motor-generator sets (Art 6) (frequency changers) to give le current for lighting. These usually consist of a synchronous motor driving an tor. If the distribution system voltage must be kept constant, some form of e regulator is installed, which will keep the voltage constant on each individual , or on the 3-phase circuit as a whole. A switchboard with the necessary switches easuring instruments is requisite. D-C SUBSTATION consists of stepdown trans- s, converters, or motor-generator sets, with incidental regulating and protective s. The converter (Art 11) is cheaper and more efficient than the motor-generator d is advisable in absence of any local reason for using motor-generators. Con- may be arranged to give constant voltage irrespective of load, or may be over- unded. The substation then resembles a d-c generating station.

htning arresters are to protect the apparatus of a station from natural ing discharges, and from "internal lightning" caused by sudden changes rrent or voltage conditions in the system itself. A lightning arrester its a current to flow from conductor to ground, whenever the potential ds the normal, and stops this current when the excess voltage ceases to This is usually done by letting the excess voltage break down a spark by means of an arc which stops as soon as the voltage drops below a critical depending upon the width of gap.

es of arresters. HORN-GAP ARRESTER is simplest and is commonly used for high es, but is not sensitive enough for moderate and low-voltage systems. It consists pper rods, bent like horns, separated by a fraction of an inch at the nearest point iverging from there. The arc starts at the small end of gap, lengthens as it rises, nally breaks. MULTIGAP ARRESTER comprises a number of small cylinders of spe- n-arcing metal, through which the circuit to ground is made. When voltage rises essive value it causes the current to jump all the small gaps in series between these ers and establishes a circuit to ground. When the potential is relieved the arcs die In more elaborate form, several groups of cylinders are arranged in parallel, and in with different resistances, to take care of potentials of different values and charac- cs. ALUMINUM-CELL arrester, the latest, best, and most expensive form, consists of k of aluminum pans, separated by an alkali electrolyte forming electrolytic cells. ch plate a film is formed, which, for reasonable potentials (200-300 volts per cell) nts any current from flowing, but with excessive voltage the film breaks down and s a large current to flow. For high voltage a large number of plates and a short gap are usually connected in series. The gap prevents a capacity-charging current flowing, but must be closed once a day to keep the film in condition.

14. Electric Distribution

inciples. Three fundamental considerations determine the cross-section weight of copper conductors for a particular purpose (see also Art 13): Voltage lost in the line, or IR drop. This depends upon the line current the resistance of outgoing and returning lines. It is important in affecting aleability of the energy and desirability of the apparatus served. It causes derable variation in the light given by lamps, and a variation in speed of ors. (*b*) Energy lost in the line due to I^2R, which represents an

money loss. (*c*) Current density in conductors. This determines their te rise, which, if excessive, causes danger of fire.

Usual loss in voltage allowed in distribution systems is less than in tr mission; it varies from 2 to 5% of the delivered voltage. In a d-c syste proper cross-section of conductor in circular mils (Table 4) is given by: (21.6 DI) + e; where D = distance one way, ft; I = current, amperes; specified loss, volts. In an a-c system the drop due to resistance of wire is ally the determining factor; reactance drop is probably negligible, as the are strung close to each other. Choice between a c and d c for distribution depends upon character of the load apparatus and the available current. motors are generally preferable, and therefore d-c distribution systems are unless the cost of the converting substation is too great.

Examples

Series-arc system (Fig 31). Problem: 80 arc lights, requiring 10 amperes at each in a 5-mile series circuit. Allow 3% loss. Voltage consumed = 50 × 80 =

Fig 31. Series-arc Distribution

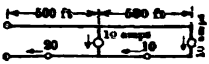

Fig 32. Multiple Distribution

Let R = resistance per 1 000 ft of wire. Length of wire in thousands of feet = 5 = 26.4. Voltage loss = 4 000 × 0.03 = 120 = 10 × 26.4 × R; hence R = 0.455. Table 4, the nearest size of wire is No 7 B & S.

Multiple system (Fig 32). Problem: two loads at 500 and 1 000 feet respectively distribution center. Each load, 10 amperes. Allowable maximum drop, 5 volts size of wire. Let R = resistance per 1 000 ft of wire. Then, 5 = 20 × 2 × 0.5 R + 10 × 0.5 R; hence R = 0.166. Choose No 2 B & S wire, of which R = 0.156.

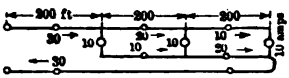

Fig 33. Anti-parallel Distribution

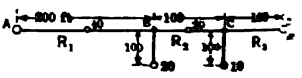

Fig 34. Tapered-conductor Distribution

Anti-parallel system. Problem: find size of wire to give a maximum drop (on m group) of 5 volts on loads shown in Fig 33. Let R = resistance per 1 000 ft of Then, 5 = 30 × 0.2 R + 20 × 0.2 R + 20 × 0.2 R + 30 × 0.6 R; hence R = Choose No 2 B & S wire.

Tapered conductor. Problem: given 3 loads as in Fig 34, and maximum dro 5 volts, to find sizes of wires. Assume drop proportional to distance: AB = 1.25, CD = 1.25. Then,

2.5 = 40 × 2 × 0.2 R_1; hence R_1 = 0.156 per 1 000 ft; choose No 2 wire.
1.25 = 20 × 2 × 0.1 R_2; " R_2 = 0.312 " " " " " 5 "
1.25 = 10 × 2 × 0.1 R_3; " R_3 = 0.625 " " " " " 8 "

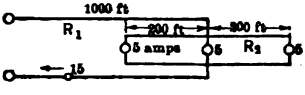

Fig 35. Feeder and Main Distribution

Fig 36. Three-wire Distribution

Feeder and main. Problem: given loads as in Fig 35, and max drop of 10 Find size of wire. Assume drop to junction point = 8 volts (0.75 of total).

Feeder, 8 = 15 × 2 R_1; hence R_1 = 0.266; choose No 4 wire.
Main, 2 = 5 × 2 × 0.2 R_2; " R_2 = 1.0 " " 10 "

ree-wire system. Principle: at any given distance from generator the sum of out- currents equals sum of returning currents (Fig 36). Problem: Given 3 loads, ad 400 ft from generator, as shown. Neutral or middle wire to be same size as out- ires. Max drop, 5 volts. Let R be resistance per 1 000 ft. $5 = 10 \times 0.4\,R + 0.2\,R + 15 \times 0.2\,R$; hence $R = 0.555$. Choose No 7 wire.

nstruction. Distribution systems may be overhead or underground. rground system costs about 5 times as much to install as the overhead, but o maintain. Steel poles are used for high voltage or regular transmission ms, but wooden poles are satisfactory for ordinary distribution. Cedar, nut, pine, and cypress are good, costing $5 to $10 per pole, according to ion. They are usually 35 to 40 ft long, have a taper of 1 in in 5 to 8 ft. to 8 in diam at top and set 5 to 8 ft in ground. Spans, from 75 to 125 ft, s are guyed to anchors on curves, at ends, and at every 20th pole, to take of breaking of wires. Glass insulators on cross arms are used for moder- voltages, porcelain insulators for higher. In stringing wires, sag must be sted with reference to the temp; a large sag in summer, small in winter.

cities most of the distribution is laid underground in elaborate conduits, which are nsive and unnecessary for mining work. Good results are obtained by laying a lead- ed double conductor cable in a shallow trench and covering it with earth.

terior wiring of buildings. Definite methods, practices, and regulations covering llation of distributing circuits are based on following considerations: (*a*) avoidance nger from fire or risk of shock; (*b*) limitation of loss of power and energy; (*c*) main- ice of reasonably constant voltage at the load; (*d*) assurance of reasonable mechani- trength; (*e*) compliance with local specific regulations. STANDARD VOLTAGES: for ing and incidental power, 100 to 125 volts; for power and lighting on 3-wire system, o 250 volts; for power alone, 550 volts. Usual allowance for drop in building wir- 2%. LOCAL REGULATIONS to be observed: National Electric Code, for obtaining ance on buildings; Municipal Inspection in cities; regulations of local Light and er Co, if energy is purchased. These regulations are so elaborate that any one ex- ing to be responsible for an installation of wiring must be acquainted with the National tric Code, on which most of the other regulations are based. ALLOWABLE CURRENT- YING CAPACITY OF WIRE. Values given in Art 3 are for rubber-covered wire installed ors. For other insulation, and for exterior work, somewhat greater current is allowed. ying out a distribution system, a CUT-OUT OR FUSE must be inserted at every junction e size of wire changes, and there must not be more than 660 watts in lamps on any fuse. Larger motor loads may be taken care of by a CIRCUIT-BREAKER.

ethods of indoor wiring. OPEN WIRING ON CLEATS. Wire must be insulated with erial resisting fire, and dampness and corrosive vapors, if present. Wires must be rated from each other and from any nearby surface by specified distances and the ts may be spaced not more than 4.5 ft apart (local regulations). No 14 is the smallest rable wire. MOLDING, either wood or metal, may be used to hold and protect wires, ifference in potential does not exceed 300 volts and the power transmitted is within ified limits. KNOBS AND TUBES. If not prohibited by special regulations, wires may ttached to knobs and run through walls in porcelain tubes; a cheap form of wiring. ONDUIT. Best but most expensive method is to run the wires in conduits, built into walls, floors, or framework of building. Conduit may be lined or not, which has a ring on amount of insulation required on the wires. Conduit may be rigid or flexible; former is better and more expensive, and is often required in large cities. ARMORED LE may be used in buildings not provided with conduits, and where very reliable in- lation is required. Lead-armored cable is used where dampness is expected.

Metering. Charges for electric energy are based upon the kw-hr, which is total integrated amount of energy delivered in 1 hr to a circuit in which the rage power is 1 kw. Cost per kw-hr varies from 1¢ in large quantities, to and 15¢ for small quantities. The ampere-hr is not an accurate measure of rgy, unless the circuit voltage remains absolutely constant.

Instrument used for measuring electric energy is the watt-hr meter, sometimes called egrating wattmeter. Electric connections are similar to those for wattmeters

measuring power. MEASUREMENT OF TOTAL POWER OR ENERGY: (*a*) in d-c or s
phase a-c circuit, by one meter having its current coil in series with the load and its
tential coil in parallel with the load; (*b*) in a 3-wire d-c or in a 2-phase circuit, balanc
unbalanced, by 2 meters connected as if in 2 independent single-phase circuits
power being the sum of the 2 readings); (*c*) in a balanced 3-phase system, by 1 m
connected in 1 of the 3 receiving circuits (its reading being
tiplied by 3) or by 1 meter connected with its current coil in
the line wires and its potential coil connected from 1 line
the neutral (total power being obtained by multiplying the
ing by 3); (*d*) in a 3-phase system, balanced or unbalanc
2 meters, connected as in Fig 37. Total power is the
the 2 readings, if the power factor be greater than 0.5, in which case
difference of the readings if it be less than 0.5, in which case
potential leads of 1 meter must be reversed, to bring the
on the scale.

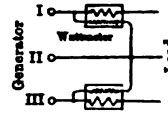

Fig 37. Power and Energy in Three-wire Distribution

Watt-hour meter comprises 3 parts: (*a*) a small electric motor, of commutator
cury and disk, or induction type, which runs at a speed proportional to the power;
brake or generator system, usually consisting of an aluminum disk revolving in the
permanent magnets to give a drag by eddy currents proportional to the speed;
of gears driving pointers for recording number of revolutions. While the type of
varies with the make and purpose of the meter, the brake and recording devices
mon to all. COMMUTATOR TYPE consists of a small d-c motor, the field being
the load current in current coil and the armature connected in potential coil
current proportional to potential. It is operative on both d-c and a-c circuits, but
only on d-c, the induction type being cheaper and better for a-c. MERCURY-MOTOR
hr meter contains a motor consisting of a disk of copper or aluminum floating in a
liquid mercury. Main current is lead to the mercury, but passes through the
cause of its lower resistance. This forms an elementary armature. Potential coils
an iron core; they form the motor field and produce a torque in the armature
volves it. Operative on both a-c and d-c circuits, but the induction type is prefer
a c. INDUCTION TYPE watt-hr meter is similar to a 2-phase induction motor, the
coils forming 1 phase, the potential coils the other. This gives a rotating magnet
which drives a metal disk rotor. Operates only on a c. Cheaper than either of the
types, and more reliable and accurate. POLYPHASE WATT-HR meter contains
coils and 2 potential coils, connected as 2 wattmeters would be connected; but
ments act on same shaft and drive same set of gears, thus mechanically taking
any positive and negative readings in either element, and giving correct total
one reading. Sometimes a single-phase watt-hr meter is used on a balanced 3-phase
cuit (such as one containing motors only). Its current coil is connected in one line
its potential coil is connected between one line and a neutral obtained by connecting
equal high resistances in Y. Total energy is 3 times the reading.

Meter capacity. In dwellings it should be 50% of the total capacity
connected load; in offices, 75%; for elevators, hoists, etc, 150% of the load.

Installation. Watt-hr meters must be installed on a rigid support free
vibration, and must be level. They should be at least 15 in between
and must not be near iron girders nor steam pipes, nor conductors carrying
currents. They must be protected from mechanical shock, weather, heat,
vermin, and dampness.

Sources of error. Adjustments are provided to take care of normal
loss. Variation in friction of brushes or bearings causes error. Mecha
shock, dirt, or dampness may alter the friction. External magnetic fields
variation in adjustment. In induction meters variations in frequency, volta
or load power factor may cause a slight error. Meters should be inspected
calibrated at least once a year. To CALIBRATE a watt-hr meter, connect it to
constant known load and count revolutions of the disk per min. Note the co
stant K painted on the disk, and substitute in formula: watts = $60 r p m \times K$.

15. Electric Lighting

ght distribution follows the law that the intensity is inversely as the square
e distance, providing the greatest dimension of the light source is less than
f the distance between source and object.

efinitions. INTENSITY of light is the relative amount of luminous energy
n by any source and is measured in candles or candle power. CANDLE POWER
is a measure of light intensity, determined by comparison with a well-
ned incandescent electric lamp, that has been accurately checked with a
dard lamp at the National Bureau of Standards, Washington. ILLUMINA-
is measured in ft-candles. One ft-candle is intensity of illumination on a
ace 1 ft distant from a source of one c p. At 2 ft distance the illumination
ld be 0.25 ft-candle. Light is the means; illumination, the end. INTRINSIC
LIANCY of a source is measured in c p per sq in. When excessive it is harm-
o the eye. Intrinsic brilliancy of tungsten lamp is 1 000 c p per sq in. A
source generally gives different intensities in different directions. Hence,
means nothing unless direction is specified. MEAN HORIZONTAL CANDLE
ER (m h c p) is the average c p of a lamp in all directions in a horizontal
e passing through center of the source, and is usually obtained by rotating
lamp about a vertical axis. MEAN SPHERICAL CANDLE POWER (m s c p) is the
age c p of a lamp in all directions, or the c p of a uniform source giving
same total flux of light. It is directly proportional to the total light given
he lamp, and is measured by taking intensity readings in all directions, or
lacing the lamp in a hollow dull white sphere and measuring average inten-
. REDUCTION FACTOR is an empirical factor for each type of lamp, by which
m h c p is multiplied to obtain the m s c p. Mean lower hemispherical c p
h c p) is the average c p in all directions below a horizontal plane through
source. LUMINOUS EFFICIENCY is expressed in watts consumed per c p
n, and the c p may be the m h c p (as in incandescent lamps) or more cor-
ly the m s c p. For arc lamps it is sometimes expressed in watts per m l h c p.
of light is measured in LUMENS, and is the quantity emanating from a source
nit intensity (one c p), and contained in unit solid angle. There are 4π or
6 lumens emanating from a source of unit intensity and 12.56 N lumens from
urce of N spherical c p.

n applying the laws of photometry to the calculation of a problem in illumina-
certain qualifications are necessary: Source of light must be small compared
he distance of the object illuminated; luminous surface must be at right angles
he line of direction from the object to be illuminated; reflection and refrac-
must be negligible. The most useful and general application of the law is
ressed by: $I_h = (c\,p + H^2) \cos^3 \alpha$; where I_h = intensity of illumination in ft-
dles at a given point p (Fig 38) on any horizontal plane;
= intensity of light source in given direction, expressed in
dles; H = height in ft of lamp above horizontal plane
taining point p; α = angle of incidence.

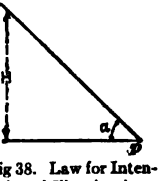

Fig 38. Law for Intensity of Illumination

eneral illumination of reasonable intensity (0.5 to 1.0 ft-
dles) facilitates a general view and perspective of the surround-
, while a greater intensity (1 to 5 ft-c) facilitates reading or
k. In DIFFUSED ILLUMINATION light comes from all directions,
ing no deep shadows; extreme diffusion gives flat lighting and
y be monotonous. To protect the eye some diffusion is usually
irable, for it tends to remove glaring reflection from objects in view; thus, when reading
n glazed paper or working on polished metals light must not be strongly directional.
DIRECT ILLUMINATION, shadows are dark, contrasts great, and forms are clearly outlined.
tails are best brought out by a light rich in the color corresponding to that of the object
wed. DIRECT LIGHTING unit sends most of its light at once to the object to be

SEMI-INDIRECT unit consists of a diffusing medium between the lamp and the object. It directs most of the light to the walls and ceiling, from which it is reflected. The INDIRECT unit directs all light from the lamp to the walls or ceiling, from which it is reflected. While more light is lost with the indirect system it is easier on the eyes. glare is avoided, the eyes are more sensitive, and vision is improved.

Arc lights are generally in large units (1 000 c p), are among the most efficient sources, but have high first cost and high maintenance cost, compared to incandescent lamps. They operate on either d-c or a-c circuits (but are not interchangeable), and may be of series or multiple type. The d-c lamp is usually a little more efficient and more reliable than the a-c. SERIES-TYPE ARCS are in series on one circuit, supplied by a generator or transformer designed to give a constant current irrespective of the lamps in operation. MULTIPLE-TYPE ARCS operate either singly or in pairs in series, on the usual constant-potential circuits with motors and incandescent lamps.

Arc lamps are also divided into the OPEN and the ENCLOSED type, the latter being preferable and are of the CARBON, FLAME, or MAGNETITE TYPE, depending upon kind of electrodes. The flame and magnetite are more efficient, the magnetite the most recent. Series arcs take from 60 to 80 volts and from 3 to 8 amperes, depending upon size; multiple lamps take 55 or 110 volts and 3 to 12 amperes. Carbon arcs have an efficiency of about 1 watt per m l h c p. Flame arc efficiency is about 0.4 to 0.7 watt per m l h c p. Magnetite arcs operate on d c, and on series circuit have an efficiency of 0.3 to 0.5 watts per m l h c p. They give off some obnoxious fumes. Arc lamps require periodic attention. MERCURY VAPOR lamp is used on d-c multiple circuits, 50 or 100 volts, efficiency 0.8 watts per m l h c p, and gives a blue-green light. No regular attention required.

Incandescent lamps are in many types, forms, sizes, voltages, and currents. There are 2 types now in general use, distinguished by the material of which the filament is made, but lamps of almost any c p and voltage may be obtained of each type. METALLIZED FILAMENT lamp (known as Gem lamp) contains a carbon filament especially treated in vacuum; it is the cheapest and most durable now on the market, the ordinary carbon filament lamp being obsolete. Gem lamp operates at efficiency of about 2.5 watts per m h c p. TUNGSTEN FILAMENT lamp (known as Mazda lamp) contains a tungsten filament giving yellow-white light. First cost is greater than the Gem, but its better efficiency usually saves enough energy to warrant the cost It is less affected by variation in voltage. Filament is more easily broken by mechanical shock or vibration than the metallized filament. Efficiency: 1.0 to 1.25 watts per m h c p. GAS-FILLED LAMPS (known in trade as high efficiency type C) have a tungsten filament coiled into a close spiral in a bulb filled with an inert gas at about atmos press. This retards distintegration of filament and permits operation at a higher temp and better efficiency (0.5 watts per m h c p). These lamps for multiple circuits are made only in large sizes, 200 watts and larger; series lamps in smaller sizes.

Rating of incandescent lamps. All multiple lamps are now rated in watts rather than c p. In speaking of the c p of incandescent lamps the m h c p is usually meant, from which the m s c p may be obtained by multiplying by a reduction factor given by makers. All incandescent lamps are very sensitive to variation in impressed voltage, respecting life, as well as efficiency and c p. Gem lamp is more sensitive than the tungsten. Common sizes of Gem lamps are 40, 50, and 60 watts, giving 16, 20, and 24 m h c p respectively. Common sizes of Mazda lamps are 25, 40, and 60 watts, giving 24, 39, and 60 c p respectively. Average useful life of a Gem lamp is 600 hr; of a Mazda, 1 200 hr. A lamp's useful life is said to be at an end when its c p for rated voltage has decreased to 80% of initial c p.

Costs. Enclosed carbon arc lamps cost $16 to $20; flame arc, $30 to $45. Magnetite arc, $23 to $27; mercury arc, with glass tubes, $33 to $35. Annual cost of OPERATING ARC LAMPS is from $30 to $70 per year, excluding fixed charges. Contracts are often made between municipalities and lighting companies for street lighting at $65 to $100 per year per arc lamp, everything supplied by

ng company. Gem incandescent lamps cost 15 to 25¢ retail; Mazda lamps, \$8. Cost of OPERATING INCANDESCENT LAMPS, including maintenance, st, and renewals, is summarized by A. G. Rakestraw as follows:

Cost of energy per kw-hr, cts	1	5	10
Cost of operation, cts per 1 000 s c p hr:			
25-watt tungsten	5.8	12	20
100-watt tungsten	4	10.5	18
Gem at 2.5 watt per c p	5.8	18	..

st per hr of supplying a given quantity of light comprises cost of lamp f energy. Following formula is convenient for obtaining minimum cost, mparing costs of different types of lamps:

$$\frac{Pn}{L}+\frac{c\,p\times w\,p\,c\times K}{1\,000}$$; C = total cost of light required, cts per hr; P = price of cts per lamp; n = number of lamps required for desired c p, obtained by dividal c p desired by the c p per lamp under consideration; L = average life of lamp, p = total c p desired; $w\,p\,c$ = watts per c p of lamps considered; K = price of cts per kw-hr.

rior Illumination. Interiors are generally illuminated by incandescent lamps on mulircuits, and to supply general illumination of even intensity a number of medium size (60 to 250 watts) are usually preferable to one large unit. Units should be placed or l so as to be out of line of sight of eye. Best method of distributing light is to divide into equal squares, having sides of 10 to 20 ft, depending upon degree of illumination l and height of ceiling, and placing a source of light at ceiling in center of each square t corners). Any local concentrated illumination may be provided by special local fix-

Diffusing globes should be used on all lamps in line of vision, and bowl frosted lamps ixtures unless completely shaded. Customary criterion for good interior lighting of ies by Mazda lamps is to supply 1 to 2 watts per sq ft of floor space; the higher value work is exacting or walls are of dark color. This is based on an illumination of from 7.0 ft-candles on a plane 30 in above floor, using tungsten lamps.

ne lighting. Tunnels, shaft stations, and all places of traffic, are usually d by 40 or 60-watt Mazda lamps, with weatherproof sockets and steel lain enamel reflectors. In gassy mines lamps are enclosed in heavy vapor-glass globes protected by iron guards. 200 to 300-volt circuits are used in , for which voltage lamps are available. Working places may be lighted rtable storage battery lamps, carried on the cap with separate battery or hand with battery combined (Sec 23, Art 10). To be approved by the u of Mines these lamps must be free from possibility of igniting gas, must light weight (not over 5 lb) and must not spill or leak electrolyte. They illuminate a 7-ft circle, give about 0.7 c p, and are usually for 2 volts au of Mines Schedule 6).

ble 11. Usual Intensities of Illumination in Installations Analogous to Those of Mining

Service	Intensity, ft-candles	Service	Intensity, ft-candles
k	4–5	Steel works:	
tory, general	0.8–1.5	Unloading yards	0.1–0.3
al bench for fine work	5–10	Open-hearth floors	0.1–0.3
al bench for coarse work	3–5	Blast furnaces	0.3–0.5
hine tools	2–5	Rolling mills	1–3
tern shop (wood)	3–5	Wire drawing	1–2
tern shop (metal)	4–6	Threading floors, pipe mills	1–2
ver house	2–3	Warehouse	0.5–1
		Wharf	0.1–0.2

Reflectors should be used with all lamps. Reflector for arc lamps for general lighting is an integral part of lamp, and designed to throw the light downward and outward. Reflectors for incandescent lamps may be extensive, intensive, or focussing; extensive throws the light downward, within a solid angle of about 90°, intensive in an angle of 60° and focussing in an angle of 30 to 40°. Industrial reflectors may be made of white enameled steel, aluminum, or painted metal; for interior use, plain glass or prismatic glass. Latter uses the principle of refraction to send downward the rays that would normally pass through the glass. Reflectors and lamps must be cleaned regularly, to prevent loss of efficiency. Tungsten lamp should be cleaned while the current is on, as there is less liability of breaking the filament.

16. Applications of Electric Transmission to Mine Service

(See Sec 16 for details of this subject.)

17. Electrochemistry

Equivalent weight or chemical equivalent of any substance is its molecular weight divided by its highest valency; thus, equivalent weight of copper in $CuSO_4$ is 31.78, being the atomic weight of copper 63.57 divided by its valency 2. Equivalent weight of the SO_4 radical is $[32.07 + (4 \times 16)] \div 2 = 48.03$. Equivalent weight gives the relative weights of various substances deposited in electrolytic work by a given current.

Gram molecule or **mol** is the number of grams of a substance which are equal to its molecular weight; thus, 1 gram molecule of $CuSO_4$ is 159.64 gm. GRAM EQUIVALENT is the number of grams of a substance which are equal to its equivalent weight; or to its gram molecule divided by its valency. The gram equivalent of $CuSO_4$ is $159.64 \div 2 = 79.82$.

Electrolyte. When an electric current passes through certain substances chemical action takes place at the points where the current enters and leaves the substance. Such substances are called electrolytes and the chemical action thus produced is called electrolysis.

Electrodes are the conductors by which the current enters and leaves the electrolyte. ANODE is the electrode by which the current enters; CATHODE that by which it leaves. The anode is connected to the positive terminal of the generator. Hydrogen and metal atoms of salts flow to cathode and are called CATHIONS; oxygen, and acid and basic radicals flow towards anode and are called ANIONS. All anions and cathions are called "ions."

Electrochemical equivalent OF AN ION is the mass in gm of the ion which would be deposited by one coulomb (Art 1) of electricity. ELECTROCHEMICAL CONSTANT or FARADAY (F) is the number of coulombs required to liberate one gram equivalent of any ion; value is 96 450 coulombs for all ions.

Faraday's Laws. Quantity of an electrolyte decomposed by an electric current is directly proportional to total quantity of electricity which passes. Rate of decomposition is directly proportional to current. Quantity decomposed is theoretically independent of voltage, current density, size of electrodes, and concentration of electrolyte. In practice local reactions cause deviation from this law. A given quantity of electricity always decomposes equivalent weights of different electrolytes in definite proportions for different elements. Total weights of different substances deposited by a given current in a given time are proportional to the equivalent weights of those substances. Some elements, as copper, may have different valencies in different combinations. Weight of such substances deposited is inversely proportional to the valency.

Electrochemical equivalent OF A SUBSTANCE is the number of gm of the substance deposited by 1 ampere flowing for 1 sec. The ampere is the unit electric current, which will deposit 0.00118 gm silver in 1 sec. For calculation

ts deposited by different currents in commercial practice it is more conven-
› use the value of grams deposited by 1 ampere in 1 hr (Table 12).
: electrochemical equivalent of any ion may be calculated by dividing
am equivalent of the ion by the Faraday. Thus, grams deposited in 1 sec
ampere equals the gram equivalent of the ion + 96 450. Weight of any
ınce in gm deposited in 1 hr is obtained by multiplying the values given in
12 by the current in amperes.

ible 12. Electrochemical Equivalents of Common Elements, in Grams Deposited per Ampere-hr

	Gm		Gm
ninum	0.3396	Lead	3.863
nine	2.981	Magnesium	0.4531
ium	0.7472	Nickel (val = 2)	1.095
rine	1.322	Oxygen	0.2984
per (val = 1)	2.371	Platinum (val = 2)	3.640
(val = 2)	1.186	Silver	4.025
l (val = 1)	7.353	Sodium	0.8576
(val = 3)	2.451	Tin	1.109
lrogen	0.0376	Zinc	1.219
(val = 2)	1.042		
(val = 3)	0.6946		

ecomposition or critical voltage is the minimum potential which must be essed to cause decomposition of a substance. With lesser potentials no n takes place; with greater potentials action is proportional to current. value depends upon chemical composition of the electrolyte, and is a func- of the chemical energy of the process.

e 13. Decomposition Voltages of Common Solutions used in Metallurgical Industries

	Volts		Volts
d, hydrochloric	1.31	Hydrate, potassium	1.67
nitric	1.69	" sodium	1.69
oxalic	0.95	Nitrate, lead	1.52
perchloric	1.65	" potassium	2.17
phosphoric	1.70	" silver	0.70
sulphuric	1.67	" sodium	2.15
loride, nickel	1.85	Sulphate, cadmium	2.03
loride, sodium	1.98	" nickel	2.09
		" zinc	2.35

alues given in Tables 12 and 13 are useful in checking efficiency of any elec- ytic action; for, with these constants, the theoretical value of grams separated kw-hr may be calculated and compared with the results obtained in practice. is, if A is the value of grams deposited per ampere-hr (Table 12), and B is the ical voltage for that substance (Table 13), then the theoretical grams per hr = $(A + B) \times 1\,000$. Example. Copper is deposited from a cupric solution he rate of 1.186 gm per ampere-hr (A), and requires 1.59 volts to maintain the on (B). Therefore the maximum possible recovery is $(1.186 \times 1\,000) + 1.59 =$ gm per kw-hr. Similarly, zinc is decomposed at rate of 1.219 gm per ampere- A), and requires a critical voltage of 2.35 (B). Hence, a primary battery con- es a minimum of $(1.219 \times 1\,000) + 235 = 520$ gm per kw-hr. The kw-hr re- red to deposit 1 kg of material are given by the formula: kw-hr = B

18. Batteries, Storage and Primary

Lead storage battery consists of 2 lead electrodes in dilute H_2SO_4. The positive plate has lead peroxide supported by a grid of pure lead; the negative is lead sponge similarly supported. The chemical reaction is:

$$\underset{\text{+plate}}{PbO_2} + 2\,H_2SO_4 + \underset{\text{−plate}}{Pb} = \underset{\text{+plate}}{PbSO_4} + 2\,H_2O + \underset{\text{−plate}}{PbSO_4}$$

(charged) (discharged)

Reading from left to right gives the action of discharging; from right to left gives charging. There are 2 types, the Planté and the Faure. PLANTÉ TYPE consists of plates of pure lead with surface increased by roughening by web ribs or grooves, and formed by charging electrolytically. There are 3 forms of construction of Planté plates: central web, cast lead, and pellet construction. In general, Planté cells are heavier and more bulky than Faure cells, but last longer. FAURE TYPE (paste type) has active material consisting of a paste containing litharge (PbO) or red lead (Pb_3O_4) applied to all grids and dried. Plates are then formed by being charged and discharged. Faure cells are lighter and therefore preferable for vehicles. Positive plates are those from which the current flows to the load during discharge. They have a dark chocolate color when charged, with hard smooth surface. Negative plates are gray, with soft surface. The ELECTROLYTE H_2SO_4, diluted with distilled or pure water, should have sp gr of about 1.15 when new, but different values are used for different services. It must be free from chlorine, nitrates, copper, iron, mercury, arsenic, acetic acid, and platinum, and should be made for the particular purpose. When cell is fully charged, the sp gr is 1.21 to 1.3; when discharged, about 1.15.

Capacity of a lead battery is stated in ampere-hr. Normal discharge current is that which the cell will give for 8 hr. Ampere-hr rating is this current multiplied by 8 for stationary work or by 5 for vehicle service.

Special ratings may be stated for a 1-hr or 4-hr discharge. Rate of charge and discharge varies from 6 to 10 amperes per sq ft of plate area, not including area obtained by corrugating. Any current may be obtained from a cell by putting enough plates in multiple. Watt-hr efficiency is the ratio of output to the input necessary to bring the battery back to its original condition. It is 90 to 92% for a battery floating on the line, and 75 to 80% for a battery completely discharged before recharging. A cell is discharged when its terminal voltage while discharging has decreased to 1.8 volts, and is charged when it requires 2.5 volts to force rated current through it. If a cell is discharged so that its voltage at normal current is less than 1.75, $PbSO_4$ may form, making it difficult to charge.

Care of lead storage batteries. All terminals and electric connections of a lead cell must be of lead; joints are formed by burning, or are lead covered. Instructions for care of batteries are given by makers, and should be followed carefully according to conditions and service. Electrolyte must be free from the injurious substances mentioned above, must be of definite sp gr for each condition, and must cover all plates. Cells must be cleaned before any deposit of sediment on bottom is high enough to touch the plates. Exterior of the cell must be cleaned and kept dry to prevent grounding and deterioration of terminals. Any leak must be repaired at once. Charge as soon as possible after cell has been discharged, at a current slightly in excess of the 8-hr discharge current, continuing until the negative plates give off gas steadily; then stop. In discharging stop when terminal voltage drops to 1.8 for normal 8-hr current and 1.6 volts for the 1-hr rate. Keep temp of the battery below 105° F. Cells to be put out of commission for some time should first be fully charged, electrolyte removed and replaced by pure water. Then discharge through a very low resistance, until practically discharged (avoiding heating of cells). Electrolyte is then removed, plates washed, dried, and put away.

ıon storage battery contains positive plates consisting of perforated steel tubes r nickeled and filled with alternate layers of nickel hydroxide and thin flakes of pure ic nickel. Tubes are supported by a grid of cold-rolled nickel steel. Negative consist of a nickel-steel grid, holding rectangular pockets filled with powdered iron

All plates are insulated from each other and from steel container. Electrolyte s of a 20% solution of potash in distilled water. Chemical reaction is:

$$\underset{+\text{plate}}{2\,NiO_2} + \underset{-\text{plate}}{2\,KOH} + Fe = \underset{+\text{plate}}{Ni_2O_3} + \underset{-\text{plate}}{2\,KOH} + FeO$$

d from left to right for discharge; from right to left for charge.

ting. Batteries are rated at the current which they will give for 5 consecu- ır. Ampere-hr rating is this current × 5 hr. Charging current is same as ırging, but time is about 7 hr instead of 5. Ampere-hr capacity is practi- independent of rate of discharge, as battery is not injured by reasonable ɔad and may be discharged to 0 volts. Watt-hr efficiency is 60 to 65%. ıge voltage per cell at normal rate of discharge (5 hr) is 1.2, varying from to 1.0 volt. During charging at normal rate voltage is 1.55 to 1.85.

ıeration. Steel containers must be insulated from each other, kept clean dry, and plates kept covered with electrolyte. Charge at 75 to 85° F; arge at 120 to 125° F. Sp gr of electrolyte should be constant at 1.2. Bat- are shipped with plates discharged, and after setting up should be charged eir normal rate for 12 hr. This overcharge should be repeated after the 30 and 60 days, and thereafter whenever electrolyte is renewed. Battery stand idle indefinitely if level of electrolyte is above the plates. It should ntilated, as the hydrogen gas given off is explosive. As in case of all stor- ıatteries the maker's instructions must be carefully followed.

eight and cost. LEAD STORAGE batteries rated on 8-hr basis cost about: ɔer kw-hr of capacity. Weight: 120 lb per kw-hr for portable style, 260 lb ıss jars, 370 lb in lead-lined tanks. Hence, they cost $300 to $400 per kw ɔity on 8-hr basis. NICKEL STORAGE batteries rated on 5-hr basis cost t $60, and weigh about 71 lb per kw-hr capacity. On this basis the cost w rating is about $300. The nickel-iron storage cell gives about 14 watt-hr ɔ of gross weight per charge; portable type of lead cell, about 10 watt-hr per lb.

imary batteries consume zinc or other metal by H_2SO_4, KOH, or similar electrolyte, ɔroduce electrical energy. Zinc is usual for negative pole, and carbon or copper for ive. Inside a primary battery current flows from zinc to carbon. Polarization ıs from new chemical substances (usually hydrogen) at the poles, causing a back . Depolarizers are chemical reagents used to combine with these substances and nt or reduce back e m f. There are 3 general types: wet, dry, and standard. WET s are being superceded by dry cells on account of their greater convenience. Typical ells are: Daniell, giving 1.07 to 1.14 volt; Gravity, 1 volt; Bunsen, 1.9 volt; Edison- ıde, 0.75 volt; LeClanche, 1.5 volt. The Daniell and Gravity are similar, and are for continuous small currents. LeClanche cell is good for intermittent service, as epolarizer takes time to operate. It is the commonest wet battery. DRY CELLS f LeClanche type, consisting of a zinc container which is also the negative pole. A ɔn rod forms the positive pole, the electrolyte being sal-ammoniac and zinc chloride in blotting paper, saw dust, or the like. Manganese peroxide is used as a depolarizer. age is 1.5 to 1.6. Internal resistance is 0.05 ohm new and 0.5 ohm after 10 months. short-circuit current through an ammeter of 0.01-ohm resistance should be from 18 to mperes. High temp increases the current. Potential decreases with age, due to dry- out. Cells are not good after 10 to 12 months, even if not used. Their ampere-hr ıcity is 24 to 30; higher on intermittent service, but capacity and life are very poor ɔntinuous service. Life of cell depends greatly upon relative external and internal ıtance, a matter requiring careful consideration. By putting 2 cells in parallel their bined life may be much more than twice the life of one alone on the circuit. Usual of cell is 6 in high by 2.5 in diam. Cost is 10 to 25¢ each, depending upon quantity quality purchased. (Standard Cell, see Art 1.)

19. Costs

D-c generators are usually of the compound-wound type, and comm 3 classes: high speed, to be belted to prime mover; moderate speed and l speed, to be direct-driven by an engine. The last class is least impor Table 14 gives costs and weights of the first 2 classes, for 125 or 250 volts.

Table 14. Weight, Cost, and Usual Speed of D-c Generators

Kw	High speed			Moderate speed		
	Speed, r p m	Wt, lb	Cost	Speed, r p m	Wt, lb	Cost
100	1 000	6 000	$ 900	625	10 000	$1 700
200	850	11 000	1 750	450	17 500	2 800
300	700	15 000	2 500	400	24 000	4 000
500	625	25 000	4 100	350	33 000	5 500

Machines to operate at lower speeds cost more. Add about 10% for install

D-c motors. Shunt motors are usually rated at the output they will continuously without injury to themselves. They are divided into classes according to their speed. Table 15 gives costs and weights of small high-speed and moderate-speed motors.

Table 15. Weight, Cost, and Usual Speed of Shunt Motors

H P	High speed			Moderate speed		
	Speed, r p m	Wt, lb	Cost	Speed, r p m	Wt, lb	Cost
0.5	2 200	60	$ 30	.....	.....	.....
1	2 000	100	50	1 675	125	$ 60
2	1 650	220	75	1 175	250	90
5	1 100	550	150	920	600	195
10	850	950	240	700	1 100	280
20	680	1 650	410	550	1 900	470
25	650	1 950	500	500	2 300	600

Cost of installation, exclusive of freight, is from 5 to 10% of first cost, depending upon local conditions.

Table 16. Weight, Cost, and Usual Speed of Series Motors

H P, nominal	Speed, r p m	Wt, lb	Cost
40	750	2 300	$440
50	700	2 650	525
75	650	3 300	640
100	625	3 700	700
150	600	5 000	950

Series motors are usually railway type, rated at output they will give for 1 hr without injury.

A-c generators and synchronous motors cost about the same for given output, speed, and voltage. Curves are given for costs usual types in Art 8. Add about 10% for installation.

Polyphase induction motors. Curves in Art 10 give costs and weights of usual sizes and types. Single-phase motors cost 25 to 30% more for given output and speed. Installation is simpler for most a-c motors, and cost can be taken at from 4 to 8% of first cost.

otor-generator sets, with 2 d-c machines, or 1 a-c and 1 d-c, cost about er kw rated output for a 200-kw set running at 750 rev per min; more for er sets. Flywheel and spe- controlled sets cost more be- of special features.

Table 17. Cost of Synchronous Converters

Kw	Speed, r p m	Wt, lb	Cost
100	750	13 500	$2 000
200	750	19 000	2 800
300	750	23 000	3 400
500	500	35 000	5 200

nverter costs are given in : 17 for a line of 25-cycle ines; 60-cycle at same speed little more expensive.

ansformers. Weights and of oil-cooled transformers for cles are given in Table 18. 25-cycle transformers cost 20 to 30% more. of installation is very small, as there are no moving parts.

18. Cost of Oil-cooled Transformers

:w	Voltage	Wt, lb	Cost
:0	2 200	450	$85
50	2 200	1 300	200
:0	2 200	1 900	275
00	13 000	2 800	450
00	13 000	5 000	700
00	13 000	6 500	900

Transmission lines for 3-phase, 33 000 volts, with No 2 B & S wire, wooden poles and porcelain pin insulators, may be erected for $1 800 to $2 000 per mile, if topography of district is not difficult

Power plants. Costs of building and equipping are: STEAM PLANTS, with reciprocating engines, vary according to size and character ant from $90 to $140 per rated kw. STEAM-TURBINE PLANTS, from $40 to er kw. HYDROELECTRIC PLANTS from $100 to $200 per kw, including dam other equipment. GAS ENGINE PLANTS, with gas producers, from $90 to per kw. In each case the lower figure applies to very large installations.

st of operation of power plants varies so widely with local conditions that detail is necessary for accurate estimates. A value of 0.5¢ per kw-hr uding fixed charges) is low, and is attainable only in large plants. 1¢ per r delivered to bus bars is common where load factor is reasonable, say 0.3 , and is a figure commonly used for preliminary estimates. LOAD FACTOR : ratio of average load for some period (as 24 hr) to maximum load during time. Duration of PEAK LOAD must be specified (as 1 min or 15 min); usually a short period during which the machinery may carry the overload ut injury. Total cost of a kw-hr, including fixed charges, is high when oad factor is low and vice versa.

1. General Principles

In structural design, one or all of 3 conditions may govern: safety, economy, esthetic effect. Safety involves knowledge of the stresses produced by the external forces acting, mechanical properties of materials of construction, and details of design best suited to the purpose.

'o compare two designs from standpoint of economy, the elements of cost are reduced common basis, using either capitalized or annual cost:

$$P = C + \frac{M}{r} + \frac{E}{(1+r)^n - 1} + \frac{R}{(1+r)^n - 1}$$

re P = capitalized cost, or the sum of money which would build and perpetually main- the structure; C = first cost; M = annual maintenance and operation; E = cost xtraordinary repairs every nth year; R = cost of renewal of structure in nth year; rate of interest. Annual cost = Pr.

line structures often have a useful life not greater than the life of the mine, and a sink- fund should also be included = $S + [(1+r)^x - 1]$, where x = useful life of structure ears. Esthetic principles are seldom considered except in important structures like ges or architectural work. Following case is also common. An addition to a plant be required n years hence and will cost A dollars. What expenditure can be afforded to avoid this future outlay? As much as the present worth of A dollars due in n s, or $p = A \div (1+r)^n$.

MECHANICS OF MATERIALS

2. Stress, Strain, and Elasticity

rain or deformation is the change in dimension produced on any material n external force; usually expressed as a ratio, inches per inch. Poisson's of lateral to direct strain is about 0.25 to 0.3 for metals. STRESS is the ance offered to deformation. For equilibrium it must be equal to the exter- orce, and may be regarded as resisting this force. It is expressed in units rce per unit area, lb per sq in or per sq ft. There are 3 kinds of strain and s: TENSION, COMPRESSION, and SHEAR. Bending and torsion are combina- of these, though sometimes classed separately.

odulus of elasticity or Young's Modulus = E = unit stress ÷ unit strain = stant (within elastic limit); or "stress is proportional to strain" (Hooke's law).

s generally considered the same in tension and compression for all materials in com- ise; a fundamental assumption in the theory of beams and columns. In shear or a = G = about 0.45 E. Hooke's law holds only for "elastic" materials (not plastic), nperfectly for C I, concrete, and some other materials. Thus, a steel bar 1 in diam in long, under tensile load of 23 000 lb (= 29 300 lb per sq in), taking E = 30 000 000, retch 29 300 ÷ 30 000 000 = 0.001 in per in, or a total of 0.012 in. If this law ntil strain = unity, the length of bar would be doubled; hence E is sometimes de- as force which would stretch a rod of unit cross-section to double its length.

stic limit is the limiting usually in lb per sq to which Hooke's law

t easily determined in test- "drop of the beam" of the machine, which occurs at ELD POINT, or commercial limit; higher than true limit (see Fig 1). Yield s not well defined in some als, as C I; it averages 0.5 the ultimate strength.

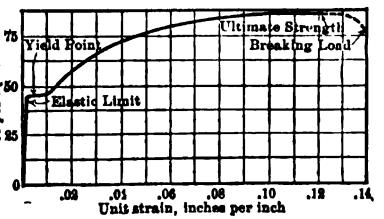

Fig 1. Stress and Strain for High-carbon Steel

mate Strength is the greatest stress, usually in lb per sq in, which a al develops before failure; sometimes greater than BREAKING LOAD. Some als in compression fail to give a true ultimate, but continue to compress crease in cross-section,

Resilience is a measure of DUCTILITY of material, and hence its ability to wit shock or suddenly applied loads. It is the work required to produce a given stres

Direct or static stresses are those acting always in one direction. REPEATED STR vary in intensity in one direction, but never pass through zero. ALTERNATING STR pass through zero, as, from tension to compression. Rupture may be caused not onl force exceeding the ultimate resistance of the material, but also by repeated ac forces of these two types, acting between certain limits which are less than the ulti known as the FATIGUE OF METALS.

Suddenly-applied loads, shock, and impact. A load is considered suddenly ap when its full amount acts instantly upon the material loaded. It produces strains stresses double those produced by a gradually-applied load. Shock is produced wh load moves freely before acting upon the material. The effect is that of a sudde applied load plus the effect of the motion. In practice suddenly-applied loads sel occur; shock is avoided if possible, but, in structures like RR bridges, an allowan effect of impact (a combination of sudden application and of shock due to irregulari roadbed, etc) is always made. It should also be allowed for in designing hoisting and links and pins for couplings.

Working stress is the max stress considered safe by the engineer and use him in designing. FACTOR OF SAFETY = ultimate strength divided by wo stress; it depends on: (*a*) uniformity, reliability, and durability of mate (*b*) kind of stress and character of loading, and certainty with which amo load is known; (*c*) character and life of structure.

For uniform materials like steel, 4 may be used; for variable materials like woo 10. Factor of safety is greater for alternating than for direct stress; less for tem structures than for permanent. In many cases (as for steel columns) safety factor s be computed on basis of elastic limit rather than ultimate strength.

3. External Bending Moments and Shears in Beams

Beams are of 4 kinds: (*a*) simple beams or horiz members, with end supp (*b*) cantilever beams, having but 1 support, or projecting from a suppo constrained beams, those having 2 supports and being rigidly fixed at both, or projecting over one or both, so that moments occur at the suppor continuous beams, with more than 2 points of support. Beams are subje bending and shear; struts or columns are subject to bending and compres

External bending moments and shears in (*a*) and (*b*) are easily determined as The derivation of formula for (*c*) is based on equation of the elastic or deflection while (*d*) involves special treatment, based on Theory of Three Moments. Table formulas for (*a*), (*b*), and (*c*); for (*d*), see *Trans* Am Soc C E, Vol 76, p 785.

End reactions must = total load, from law $\Sigma V = 0$. Also $\Sigma M = 0$; hence may be found by taking moments about either support.

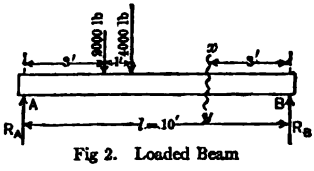

Fig 2. Loaded Beam

Example, Fig 2, M about A = (2 000 + (4 000 × 4) = R_B × 10, or R_B = 2 and R_A = 2 000 + 4 000 − 2 200 = 3 80

Bending moment at any sectio algebraic sum of moments of all for left of the section, calling forces t to cause clockwise rotation positive others negative.

In Fig 2, bending moment at section xy = (3 800 × 7) − (2 000 × 4) − (4 000 = + 6 600 ft lb, and also equals 2 200 × 3, or the moments to the right, if clockwise be called plus.

Vertical shear. At any section in a beam 2 equal and opposite forces ac acting, one on right and one on left, tending to shear the beam at that Vertical shear at any section is equal to algebraic sum of forces to the l

ection, upward forces being taken as positive, downward forces, negative. es to right of section may also be used, changing the sign.

Fig 2, vertical shear at $xy = 3\,800 - 2\,000 - 4\,000 = -1\,200$ lb. Fig 3 shows nts and shears at different sections of a beam.

aximum moments and shears. Max moments and shears determine the -section of a beam. It is generally economical to use same cross-section ughout, hence max moments shears need be uted. Point ax moment is l from princi- own in Fig 3; curs where ar passes gh zero. Max occurs at sup- .

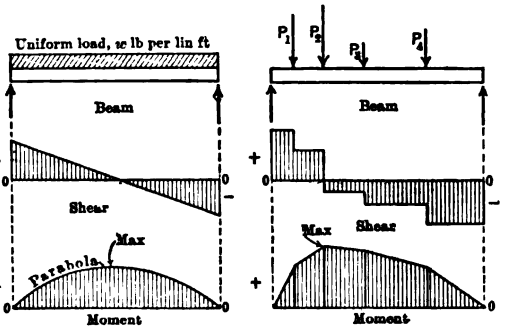

Fig 3. Graphic Representation of Moments and Shears in a Beam

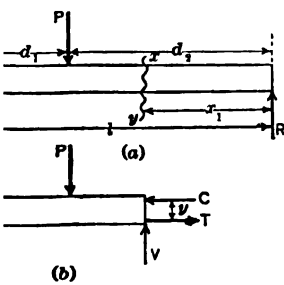
lesigning struc- for moving a series of con- ted loads is similar in spac- nd amount to rs or moving load to be used. These loads may be moved to occupy different posi- and the max moment is determined by methods in Art 19.

le 1 gives formulas for reactions, max bending moments, moments at any section ax deflection (for uniform cross-section), for common forms of beams and loading.

4. Flexure of Beams

beams, when subjected to loading, are stressed in tension, compression and . Vertical loading produces vertical shear, causing equal horiz shearing , which give to the horiz fibers of the beam their tension and compression es. Investigation of beams is based on the 3 laws of equilibrium (Sec 36, 2), the external forces being usually coplanar and at right angles to beam.

s, if beam in Fig 4a be cut at any section xy, the bending moment at $xy = P d_1 x_1$ nd shear at $xy = P d_1 \div l$ (Art 3). This moment must be resisted by the inner forces of beam acting on the right of section xy, or 2 forces C and T (both equal since ΣH must = 0) and acting with lever arm y. Assuming E equal in tension and compression, and that Hooke's law holds, and that plane sections of a beam before bending remain plane after bending (Navier's hypothesis), then it may be shown that C and T are the resultants of uniformly varying stress acting over the upper and lower sections of beam, having 0 intensity at a horiz plane passing through the center of gravity of section (known as the NEUTRAL AXIS), and max intensity at the extreme fibers of beam, directly proportional to distance of these fibers from neutral axis. The internal, or RESISTING MOMENT, is then $= kI \div d = kS$, where M is in inch-lb, k = extreme fiber stress, lb per sq in, I = it of inertia of the section, in^4, d = distance from neutral axis to extreme fibe $S = I \div d$ = SECTION MODULUS.



. Bending Moment in Simple Beam

Table 1. Reactions, Bending Moments, and Deflections of Beams

SIMPLE BEAMS. REACTIONS, BENDING MOMENTS AND MAX DEFLECTION (FOR UNIFORM CROSS-SEC)			
Beams and loading	**Reactions**	**Bending moments**	**Max defl'n $I=\infty$**
w = lb per linear ft	$R_A = R_B = \frac{1}{2} wl$	$M = \frac{1}{2} wx(l-x)$ $M_{Max} = \frac{wl^2}{8}$	$\frac{5wl^4}{384EI}$
	$R_A = R_B = \frac{1}{2} P$	$M = \frac{1}{2} Px$ $M_{Max} = \frac{1}{4} Pl$	$\frac{Pl^3}{48EI}$
	For AC $R_A = \frac{d_2}{l} P$ For BC $R_B = \frac{d_1}{l} P$	For AC $M = \frac{Pd_2}{l} x_1$ For BC $M = \frac{Pd_1}{l} x_2$ $M_{Max} = \frac{Pd_1d_2}{l}$	[illegible]
	For AC $R_A = R_B = P$ For CD $R_A = R_B = P$	For AC $M = Px_1$ For DB $M = Px_2$ For CD $M = Pd$ $M_{Max} = Pd$	$\frac{Pd}{24EI}(3l^2 - 4d^2)$
	$R_A = R_B = \frac{1}{2} W$	$M = Wx(\frac{1}{2} - \frac{x_1}{l^2})$ $M_{Max} = \frac{Wl}{8}$	$\frac{Wl^3}{60EI}$
	[illegible]	[illegible]	[illegible]

CANTILEVER AND RESTRAINED BEAMS. REACTIONS, BENDING MOMENTS AND MAX DEFLECTION (FOR UNIFORM CROSS-SEC)			
Beams and loading	**Reactions**	**Bending moments**	**Max defl'n $I=\infty$**
w = lb per linear ft	$R_A = wl$	$M = \frac{wx^2}{2}$ $M_{Max} = \frac{wl^2}{2}$	$\frac{wl^4}{8EI}$
	$R_A = P$	$M = Px$ $M_{Max} = Pl$	$\frac{Pl^3}{3EI}$
w = lb per linear ft	$R_A = R_B = \frac{wl}{2}$	$M = \frac{wl^2}{6}(\frac{1}{l} - \frac{x}{l} + \frac{x^2}{l^2})$ $M_{Max} = \frac{wl^2}{12}$ at supports	$\frac{wl^4}{384EI}$
	$R_A = R_B = \frac{P}{2}$	$M = \frac{Pl}{2}(\frac{x}{l} - \frac{1}{4})$ $M_{Max} = \frac{Pl}{8}$	$\frac{Pl^3}{192EI}$
w = lb per linear ft	$R_A = \frac{3}{8} wl$ $R_B = \frac{5}{8} wl$	$M = \frac{wx^2}{8}(\frac{3}{4} - \frac{x}{l})$ $M_{Max} = \frac{wl^2}{8}$ at B	$\frac{wl^4}{192EI}$
	[illegible]	For AD $M = [illegible]$ For DB $M = [illegible]$	[illegible]

Example. Assuming a T-section (Fig 5), subjected to external bending moment of 9 000 inch-lb, I is found = 2.81, the center of gravity being 2.09 in from bottom and 4.91 in from top, giving extreme fiber stress in compression, $k = dM \div I = 9 \times 2.09 \div 2.81 = 2\,900$ lb per sq in, while for tension side, $d = 2.09$ and $k = 6\,700$. For a symmetrical section, k is equal in tension and compression. In design, the greatest value of k must be used. For moments of inertia of various sections see Art 26 and Sec 56, Art [illegible]

Working value of k used in design is found by reducing by a proper factor of ty the k found by testing a beam to failure. Value at failure is the MODULUS RUPTURE, and is computed on assumption that above equation holds to failure tually true only to elastic limit), since M, I and d known.

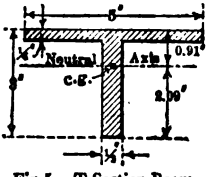


Fig 5. T-Section Beam

he work of actual design is facilitated by tables giving ies of S for different beam sections. Instead of S, the FF OF STRENGTH is often given. Thus, assuming M in , let C = coeff of strength = 8 M (= Wl for uniform ing or 2 Wl for concentrated, where W = total load, lb, l = span, ft), then C = ⅔ kS; and, knowing value of C ny beam, the safe load is easily computed, or vice versa. in ft-lb.

hear. In Fig 4*b*, a force V, equal to the vertical shear, must be applied at ion xy for equilibrium. $V \div$ the area of cross-section of the beam = v = the rage intensity of shearing stress, and the max intensity = 3 $v \div$ 2 or 3 $V \div$, and occurs at the neutral axis, where b = breadth and h = depth of beam.

sually, the limiting factors in design are axial tension and compression, it being unssary to increase size of member because of shear. In short or relatively deep beams, r may become the limiting factor, and in short timber beams especially, due to lamid structure, horiz shear often controls. Diagonal stresses are only important in reinɔd concrete beams (Art 14).

5. Columns and Struts

ompression members may be divided into 3 classes, depending upon mode of ire, and this in turn depends on the ratio of length of column to its least US OF GYRATION (Sec 36, Art 42), or in solid sections to its least diam, exsed as $l \div r$, where l = length, in, and r = least radius of gyration, in (Art 28).

hort columns, in which $l \div r$ is less than 10 or 15, generally fail by compresonly, and are sometimes termed short blocks. The safe working stress in pression is used in their design.

ort blocks are tested for determining strength of materials in compression; most rete and many timber columns fall in this class. They fail by compression or by ring in a plane making an angle of slightly over 45° with the axis of block. Shear re occurs when resistance to shear is less than 0.5 resistance to direct stress, as comion induces shearing stress on all oblique planes and max intensity (= 0.5 that of the t stress) on a 45° plane. Hence length of test specimens should always be stated, and rally will be 3 times breadth; many tests fail to agree, due to use of variable lengths.

rdinary columns, in which $l \div r$ ranges from 40 to 120, fail by combined pression and bending. Two kinds of formulas are used: (*a*) those derived theory, in which proper constants are inserted from tests; (*b*) empirical ulas, from tests only.

or column design, see Art 14, 21, 28. For eccentric loading, see Art 6.

e most widely used of the first kind is Gordon's or Rankine's formula (demonstrated by Tredgold): $P = cA + \left(1 + a\frac{l^2}{r^2}\right)$, where P = ultimate strength, lb; A = area, ; l and r as above, and c and a are constants depending upon kind of material, and l a depending on the condition of fixity of the ends of column. This formula may be for design by reducing P by a proper factor of safety.

eoretically, the strongest column has flat ends, a column with round or pin ends h is free to bend and not restrained at the ends being only 0.25, and a column with end round and one end free only about 0.5 as strong. Practically, pin-end columns ar to be as strong as flat-end, probably due to difficulty in getting an even distribut: ading and the resulting eccentric stress with the latter. Hence a should be d ɔd by tests of both flat and pin-end columns.

The principal formula of type (b) is the STRAIGHT-LINE FORMULA, so called because a graph is a straight line. This line is obtained by plotting, for a series of tests of columns of one type, the ultimate strength and $l \div r$ ratio, and drawing an aver line through the points. The general form is $p = A - B(l \div r)$, where $p = P \div A$ = intensity of stress, and A and B come from the tests. This formula is widely used, often displacing the Gordon. As before, p is properly reduced for design.

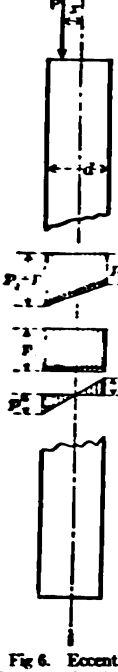

Fig 6. Eccentric Loading of Columns

Long columns, in which $l \div r$ exceeds say 200, are barred in structural practice and will not be discussed (2).

6. Torsion and Combined Stress

Torsion, a type of shearing stress, is fundamental in the design of shafts and other members subjected to a twisting moment. For circular section the formula is $d = 1.72 \sqrt[3]{M \div s}$, where d = diam, in, of a shaft capable of resisting a twisting moment M, in-lb, with a max torsive shear in the extreme fibers of s in-lb per sq in.

Example. Assume a working torsive shearing stress of 8 000 lb per sq in, in designing a circular shaft to carry a twisting moment produced by a force of 2 000 lb acting with a lever arm of 48 in. Then $M = 2\,000 \times 48 = 96\,000$ in-lb, and from the formula $d = 4$ in. nearly.

Combined stress is the condition of stress occurring when a member is simultaneously subjected to 2 of the 3 elementary forms of stress. A common case, compression and bending, occurs in the eccentric loading of columns and joints in foundations of masonry structures.

Eccentric loading of columns. Whenever possible in column design the load is applied to coincide with the axis of the column. Through use of brackets, some columns are loaded at a distance from the axis, as in Fig 6. This increases compression on left and decreases it on the right, and must be provided for by increasing the section until the maximum stress does not exceed the allowable. The unit compression due to direct stress $= p_0 = P \div A$. The unit bending stress caused by the moment $M = Pz$ will be $p' = Md \div 2I$, where I = moment of inertia of the section. Max unit stress $= p = p_0 + p'$, and must not exceed the safe value. Minimum stress $= p_0 - p'$. These formulas, though in common use, are only approx, as increase in stress due to deflection is not considered. (See Art 8 for foundations.) Combined stress also occurs in inclined bridge members, as eye bars and chords, which are subjected to bending due to their own wt as well as the direct stress of tension or compression. The common method of procedure is similar to that given above. Shafts also frequently act under the combined stress of torsion and bending (as in drum shafts of hoisting engines).

FOUNDATIONS

7. General Considerations and Bearing Power of Soils

Failure of foundations is generally caused by use of empirical rules instead of fundamental principles and poor judgment of designer.

Requisites of foundations: (a) They should be leveled off approx at right angles to the direction of loading. This insures that no component of the press will be tangential to the foundation surface, hence no tendency to sliding. Natural inequalities in rock surfaces usually hold the footing in place and make expensive stepping unnecessary. (b) When built on earth, design should be such that center of press and center of base coincide.

ining walls, it is too costly to adhere to this rule; low foundation pressures are required settlement is common. On rock little or no settlement can take place. (*c*) Each idation for separate parts of a structure supported at several points, as walls and in- r columns in a building, should be so designed, when on a compressible material, as to ubjected to pressure intensities that will cause uniform settlement.

afe bearing value of a soil depends on the character, depth, thickness and e of strata, degree of confinement, amount of moisture, type of structure and ribution of pressure.

rdinary soil is more compact as depth increases. Permanent foundations should be ed below frost level, and be well drained. Inclined clay strata frequently "crawls" r heavy loading, especially when moist. Some foundations have been entirely satis- ory on poor materials until nearby excavations have allowed the material to be forced laterally, when excessive settlement has resulted. Some settlement is generally to be cted except on solid rock, and in high structures, as chimneys, where unequal settle- t would be dangerous, very low unit press should be used. In foundations on rock, all portions of rock should be removed and filled with concrete.

earing power of soils. Table 2 is useful in forming an idea of safe unit sures, in absence of data from actual test.

Table 2. Safe Bearing Power of Soils (tons per sq ft)

Character of rock or soil	Authority

here data is entirely lacking, test pits and borings should be made, and if necess earing power of the soil tested by loading an area to point of settlement. Time rtant factor in such tests, and a safety factor of 3 to 6 should be used.

8. Ordinary Footings and Foundations

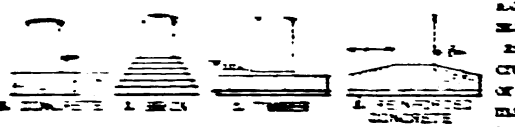

Fig 7. Footings for Masonry Walls

Table 3. Safe Bearing Pressures, Tons per Sq Ft. To get R multiply tabular value by thickness of footing in ft. Factor of safety = 10

Footing	Safe R, lb per sq in	Pressure, tons per sq ft			Footing	Safe R, lb per sq in	Pressure, tons per sq ft		
		0.5	1	2			0.5	1	2
Blue stone	300	4.1	2.9	2.0	Brickwork (Portland cement)	90	1.7	1.2	0.8
Granite	180	3.1	2.2	1.5	Concrete, 1–3–6	20	1.0	0.7	0.5
Limestone	150	2.8	2.0	1.4	Timber	1 000	7.5	5.3	3.7

Fig 7d shows a reinforced concrete footing that may be designed as in Art 14. Experiments indicate that the shear should not exceed the allowable at a distance d from face of wall; hence d is usually greater than required for bending, being fixed by d' which depends on shear. When the required offset l must be large to keep unit pressure low, large excavations of masonry and deep excavations are avoided by using a grillage consisting of 2 or more layers of timber or steel beams (18), or a reinforced footing with rods in both directions.

9. Pile Foundations

Bearing power of a soil may be increased by: (*a*) excavating to greater depth, the soil being then more compact, unless wet; (*b*) by drainage, usually by tile drain; (*c*) by wood or concrete piles.

Wood piles are used for both temporary and permanent foundations, and where the water level will last indefinitely. In temporary work, as trestles, the pile serves the purpose of both foundation and column. Oak, pine and spruce are in common use, depending upon difficulty in driving, length required, and purpose, oak being good for hard driving or where pile is subjected to abrasion. When the soil is very hard, piles are shod with iron shoes and the butt is chamfered off and banded with iron 0.5 to 1 in thick and 3 or 4 in wide. Special driving caps, with a tapered recess, are also effective. Wood piles should generally be at least 6 in diam at point (preferably 8 in) and about 12 in at butt (not over 18 in).

ncrete piles are cast-and-driven or cast-in-place. They are for permanent construc- where excavation to water level, required for wood piles, would be too costly.

fe load for a pile depends upon skin friction on sides of pile, and bearing power of soil r the point. Formula for driving wood piles: P (safe load, lb) $= 2\,Wh + (s + a)$, e W = wt of hammer, lb, h = fall of hammer, ft, s = aver penetration under last blows, in, and a = 1 for a drop and 0.1 for a steam hammer. It is applicable only in rm material, where S decreases at uniform rate. Sometimes S may be very large, after allowing the pile to stand for a day, many blows are necessary to move it at all. sual conditions require tests to determine safe loads. Max load per wooden pile is t 20 tons. Concrete piles are usually jet-driven, and above formula cannot be used. should be tested, and should carry loads of 25 to 80 tons each. Piles driven through to hard material act as columns and are computed as such.

acing of piles. They should not be closer than 2.5 ft centers. Earth is excavated 2 in below top of piles and space between them filled with concrete, which is continued depth of 12 in over top of pile.

st. Wood piles, 15 to 35¢ per ft in place; concrete piles aver 4 or 5 times as much.

MASONRY AND CONCRETE STRUCTURES

10. Lime, Cement, and Mortar (7)

mmon lime should be free from cinder and clinker, and unslaked lime should be in s with little powder or dust. Powder or dust usually indicates air-slaking, which is riment to perfect slaking later, although some fresh limes come in small pieces. Lime ld slake readily to a fine, smooth paste, without residue. Lime should be stored in a place. When slaked the paste may be kept indefinitely under water or protected air. If exposed to air in a thin layer lime may be slaked to a dry powder, sold as LATED LIME. HYDRAULIC LIME is not made in U S, and is rarely used for cement. mon lime costs about 50¢ per bbl in bulk, or 70¢ in bbls.

ment is of 3 kinds, Natural, Portland, and Pozzulan. NATURAL CEMENT is calcined nt rock, containing proper proportions of lime and clay, ground to a fine powder. It t now used for structures requiring great strength, having been superseded by Port- cement, which costs but little more and is stronger. It is made principally at Rosen- N Y, hence sometimes called Rosendale cement. PORTLAND CEMENT is made by ling to a fine powder the clinker from calcining to incipient fusion a powdered mixture operly proportioned lime and clay materials. Powdered limestone mixed with clay be used, also cement rock and clay or limestone, marl and clay, limestone and slag. uction in U S has increased rapidly since 1897, and over 100 million bbl are now pro- d annually. Cement is sold in bbl, paper or cloth bags or in bulk, the aver price at nills being 75 or 80¢ per bbl. There is an extra charge of about 7¢ per bag, which unded if bags are returned. Extra charge for bbls is about 20¢. Wt of Portland nt averages 100 lb per cu ft. A bbl weighs 376 lb; a bag, 94 lb. A bbl contains about u ft. Natural cement weighs 265–300 lb per bbl and 90–100 per bag. POZZULAN NT proper is made by grinding hydrated lime and pozzulan, a volcanic material occur- near Naples, and used by the ancient Romans. SLAG CEMENT is now the most impor- of this class. It is likely to contain much sulphur, and hence is not suited for use e air, though it is satisfactory where constantly exposed to moisture. Its manufac- is decreasing, due to use of slag in making a true Portland cement, with which it d not be confused, and which differs in no essential way from other Portland.

sting cement. Cement for small-scale work is usually bought "on brand"; that is, ke of cement that is known to have a good record for quality. It is well to specify the cement shall meet the specifications of the Amer Soc of C E, and on large works quire that all cement be tested. Complete testing requires considerable skill and ratus. Simple tests in the field may be made as follows: SOUNDNESS. Knead 1 cupful ment for 1.5 min with enough water to make a paste. Make into round pats about 3 im and 0.5 in thick, with thin edges. Make 3 of these on pieces of window glass [illegible] q. (*a*) Cover 1 pat with piece of wire netting and a wet cloth (moist air); (*b*) 1 at to action of steam for 5 hr; (*c*) put 3rd in water. Reject cement if any pat

radial cracks at edge (do not confuse with harmless shrinkage cracks), or curl or crum... (do not confuse curling with lifting of pat from glass due to expansion in setting, harmless). The air pat should not change color. FINENESS. Sift 5 oz through a 100-mesh screen; not over 0.5 oz should be retained. PURITY. Put as much cement as can be placed on a ... piece in a dish; add 0.5 teaspoonful of water and cover with clear HCl acid. Pure Portland cement will effervesce slightly, give off a pungent odor, and form bright yellow ... Powdered limestone used as adulterant will cause violent effervescence. Sand will remain undissolved in form of sediment.

Mortar. The sand should be coarse, clean, free from dust, soft particles, vegetable loam or other organic or deleterious matters.

Lime mortar. The lime should first be slaked, and the sand then spread evenly ... the paste and thoroughly mixed with it, a little water being added occasionally, until ... mortar is of uniform color. Sand reduces cost of mortar and makes it stronger ... grains being stronger than the lime), divides the lime into thin films which may more readily absorb CO_2 from the air, and prevents excessive shrinkage cracks due to water in the paste. Slaking should be done with care. The lime should be spread in 6 or ... layers in a box, or a basin in the sand, and 2.5 to 3 times its volume of water added at once. Cold water added later hinders slaking. The mass should be stirred, if at all, in such manner as to avoid chilling it. Lumps sometimes come to surface, due to formation of ... and are said to "burn." These should be broken up and pushed below surface. Slow slaking gives a volume of paste 3 or more times that of lime, while without care less than ... volumes may be obtained. Unslaked particles are not particularly harmful for masonry, but if cement is used with lime at least 2 days are required after slaking. For plastering work it should be stored 6 or 7 days. Proportions used are 1 volume paste to 3 sand, best obtained by trial. Thus, if mortar cannot be lifted up with the mixing hoe when handle is almost horiz, it contains too much sand and is "short"; if it will not slide from hoe, it contains too little sand. The proper proportions give a mortar that works easily with a trowel in laying up brick or stone. Lime mortar is unsuitable for thick walls or walls not in contact with air. 1 bbl of lime makes about 2.5 bbl or 0.3 yd stiff lime paste and 1 bbl of paste with 3 of sand about 3 bbl or 0.4 cu yd good lime mortar. 1 bbl ... slaked lime therefore makes about 0.95 yd of 1 to 3 mortar.

Cement is used neat in form of GROUT (in setting column bases, etc); in proportions 1 volume cement to 2 of sand as mortar for masonry work requiring great strength, and ... 3 for ordinary foundation work. It is not commonly used for brick walls ... to difficulty of handling it with ... trowel, but addition of 5 to ... hydrated lime makes the mortar "slick" and easy to work, though ... may cause efflorescence. Strength of cement mortar depends upon proportions and kind of sand used. A coarse sand, preferably silicious, should always be used, as fine sand kills ... cement and gives poor mortar. Sand consisting of ¼ coarse particles and ... medium fine is stated to give best results. Sharp, angular sand generally gives a stronger mortar than round sand, but has more voids and hence requires more cement for a ... strength. The denser the mixture, the greater the strength for a given volume of cement; thus the sand which produces the smallest volume of plastic mortar for the same quantity of ... materials is best. Small quantities of clay in the sand may increase the strength of a lean mixture, but decreases the strength of a rich mixture. Fig 8 shows aver strength of mixtures with different sands.

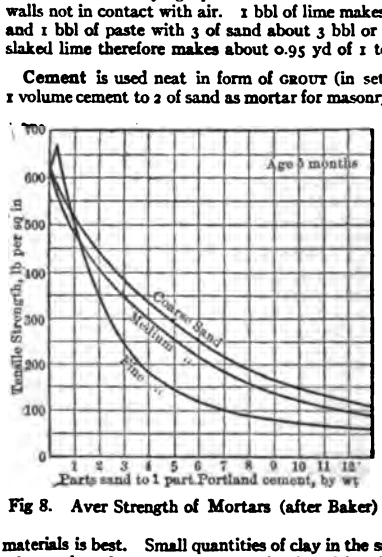

Fig 8. Aver Strength of Mortars (after Baker)

Table 4. Cement and Sand Required for 1 Cu Yd Mortar (37% voids)

Volume of mixture	Portland cement		Natural cement		Volume of mixture	Portland cement		Natural cement	
	Cement, bbl	Sand, cu yd	Cement, bbl	Sand, cu yd		Cement, bbl	Sand, cu yd	Cement, bbl	Sand, cu yd

11. Stone Masonry (7)

Engineering requirements for building stone are cheapness, durability and strength. n general, building stone should be dense, hard and of uniform texture; it should contain o seams or "drys." A fresh fracture should be bright, sharp and clean, with no loose rains. Destructive agencies acting on stone may be frost, wind, fire, pressure and fric-on; for all of these except fire, granite is the most durable; for fire, sandstone is least ffected. Chemical composition and porosity are also important.

	Wt, lb per cu ft	Aver crushing strength of cubes, lb per sq in	Modulus of rupture, lb per sq in
Granite.....	167	19 400	1 850
Limestone.....	158	9 400	1 370
Marble.....	170	12 700	1 390
Sandstone	139	9 300	1 380

Stone for masonry comrises QUARRY-FACED, used as comes from quarry; PITCHACED, face edges are pitched o a right line; and CUT STONE, epending on finish of front r face of the work. Masonry ay be classified according o continuity of courses into: ANGE, BROKEN RANGE and ANDOM. It may also be divided into classes depending on thickness of joints, that is, ie degree of care with which the stone is dressed and joints made. Cut-stone masonry, ith joints less than 0.5 in thick, is known as ASHLAR; when stones are squared to give ll joints, it is SQUARED-STONE masonry and when composed of unsquared stone it is UBBLE.

For walls the largest stones should be put in the foundation, for strength, large bearing rface and to lessen danger of unequal settlement. The stone should be laid on its oadest face; stratified stone should be laid with its bedding planes normal to the press nd the courses should also be so laid; HEADERS should be placed at frequent intervals to ND the wall transversely, and stones in adjacent courses should break joint vertically o give longitudinal strength. Porous stone should be wet before being laid. All spaces etween stones should be filled with spalls and mortar. Hammering or sliding stones on wall under construction is not allowable.

Following points are usually covered in specifications for rubble masonry: stones ughly squared; laid in irregular courses in natural bedding plane; footings of selected at stones; at least 0.2 of face and back to be headers arranged to interlock; all voids lled with concrete or small stones fully bedded in mortar.

In building walls, a 4-in veneer of cut stone is sometimes tied into the backing (usually rick) by galvanized-iron wall ties or clamps. Riprap is loose stone, piled around piers, r on faces of earth dams, to prevent wash. Hand-laid riprap is a paving of stones, laid on dge. Dry rubble is laid without cementing material. Rubble concrete is concrete in hich large stone have been embedded.

Aver amount of mortar per cu yd required for 1 cu yd of rubble is: for small ugh stones, 0.33 to 0.40; for large stones, roughly dressed, 0.20 to 0.30 cu yd.

Safe loads for best rubble are 10 to 15 tons per sq ft; for squared stone, 15 to 20; for mestone ashlar, 20 to 25; for granite ashlar, 25 to 30 tons per sq ft.

Cost of stone masonary varies with type of masonry, thickness of wall, and location of ork. Rubble usually costs $2 to $6 per cu yd.

12. Brick and Brickwork (7)

Bricks are made from mixtures of lime and sand or cement and sand.

Varieties of clay brick. COMMON BRICK is used for ordinary construction. Best brick, when broken in two, shows a fine, uniform texture, deep salmon color, contains no fissures, air bubbles, pebbles nor lumps of lime. It should also have plane faces and parallel edges (no warping), and give a clear ringing sound when struck (thorough burning). Usual size is 8.25 × 4 × 2.25 in. Overburned brick is dark in color and liable to be warped and brittle. Light or yellow color indicates soft or underburned brick. PRESSED BRICK is brick molded under heavy press. It is uniform in shape and of greater density, absorbing only 10 to 20% of its wt of water, while common brick may absorb 30 or 35%. It is used for exterior faces of walls, or where neat finish is desired. ENAMELED BRICK is made from clay containing a large amount of fire clay, on which a surface finish of enamel is placed either before or after burning. GLAZED BRICK is produced by applying a slip to the unburned brick, which adheres to clay and holds a glaze composed of readily fusible materials giving a vitreous surface. FIREBRICK is of fire clay burned at a high temp. Good fireclay is free from pyrites, lime, and other ingredients which would cause swelling or vitrification. Fireclay brick should be of uniform color, white or white speckled with brown throughout; should be laid in thin paste of fireclay, with joints as thin as possible. SAND-LIME BRICK is generally pure white. Made by molding 4 to 6% of finely-powdered lime with silica sand. The brick is then put in a tight cylinder, and heated by steam for about 10 hr, causing formation of silicate of lime, which gives hardness. Generally not as strong as clay brick, but strong enough for ordinary purposes. CEMENT BRICK is of sand, with Portland cement as the binding material.

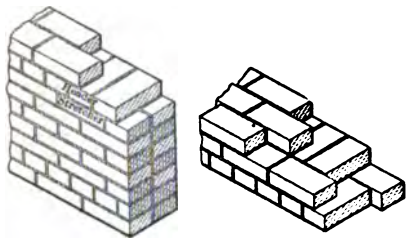

Fig 9. Bonds for Brickwork

Bond results from laying brick in such manner as to tie the wall together longitudinally and transversely. Fig 9 shows the common bond, consisting of 4 to 7 courses of STRETCHERS to 1 course of HEADERS, the latter tying the wall together transversely. For equal strength in both directions use 2 stretcher courses to 1 header course. In laying brick vertical joints in header courses must be made of such thickness that they will not come over a joint in the stretcher course. Brick should be thoroughly wet before laying; otherwise they will absorb moisture from the mortar, and prevent proper setting. Joints should be ¼ to ⅜ in thick, and for best work brick should be placed on a full mortar bed and shoved into place ("shove joints"). All vertical joints should be thoroughly "slushed" with semi-liquid mortar, so the brick will be well embedded. Face of the wall may be finished with either flush, struck or weather joints (Fig 10). For outside walls, exposed to weather, finish (c) is most durable, but more difficult to make than struck joint.

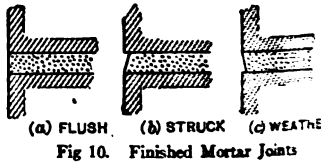

Fig 10. Finished Mortar Joints

Number of brick required depends on size. For common masonry 1 cu ft generally requires 20 brick; 1 cu yd, 500 to 600 brick. A 4-in wall (1 brick thick) requires 7; 8-in (2 bricks thick), 14; 12-in (3 bricks thick), 21 brick per sq ft of wall. An "8-in wall" actually measures 8.25 to 9.5 in, and a "12-in wall" 12.5 or 13 in.

Quantity of mortar. For aver joints (¼ to ⅜-in) 1 cu yd common brickwork requires ¼ to ½ cu yd mortar, or about 0.5 cu yd per thousand brick. For 1 to 3 Portland cement mortar, this requires about 1 bbl cement and 0.5 cu yd sand per thousand.

Working stresses for compression are: for common brick in Portland cement mortar, 175 lb per sq in; in natural cement mortar, 150; in lime and cement mortar, 125 in lime

ortar, 100 lb per sq in. **Brick piers** may be designed by the formula, $p = P - 6H + D$, here p = allowable unit stress, lb per sq in; P = allowable direct compressive stress, per sq in; H = height, in; D = least thickness of pier, in.

Costs. Common brick are sold by the thousand (M), aver price being \$6 to \$7 per M. ne bricklayer will lay 1 500 to 2 000 brick per 10-hr day, in straight thick walls, but only 0 to 500 for work involving many corners or angles. With bricklayers at 60¢ per hr d labor at 17.5¢, labor cost is \$7 to \$9 per M.

13. Concrete (7)

Composition. Concrete is a mixture of broken stone, gravel, cinders, or slag, lled the COARSE AGGREGATE, and sand or stone screenings, known as the FINE GREGATE, with a cementing material, as cement or asphalt. For reinforced important work, Portland cement is used; for unimportant work or where wt the essential element (as anchorages for suspension bridges), natural cement; phalt is used for sidewalks, floor finish and pavements.

Strength of Portland cement concrete, for a given aggregate, increases with increase in ount of cement. Concrete takes say 6 months to attain its full strength. Quantity of ter used in mixing influences the strength, and the rapidity with which full strength is ched. Dry mixtures mature quicker than medium or wet. A medium mixture ulti- tely attains about the same strength as a dry one, but, where strength is important, ry wet mixtures should be avoided as the strength is permanently affected. Strength greatly influenced also by size and grading of the aggregate (Fig 11). Strongest con-

(a)	(b)	(c)	(d)	(e)
Solid Stone Voids = 0% Density=1.00	Sand Voids = 45% Density=0.55	One size stone and sand Voids = 40% Density=0.60	Two sizes of stone and sand Voids = 35% Density=0.65	Graded stone and sand Voids = 30% Density=0.70

Fig 11. Grading of Aggregate in Concrete

te is made by using the densest aggregate, with just enough cement and water to fill the ids. Hence, it is desirable to use: 1, a graded aggregate; 2, as large size stone as prac- able; 3, no more mortar than needed to fill all voids and prevent "honey combing"; 4, more water than necessary. For massive work 3-in maximum size stone is desirable; foundations, 2.5 in; for arch rings, 1.5; for coping, bridge seats and thin walls, 1; for nforced concrete beams or slabs, 0.75 in. Fine aggregate is a relative term, applied to terial less than 0.25-in size. For sand the same rules apply as for mortar (Art 10). The irse aggregate should be graded in size, clean, hard, durable, and contain no soft, flat elongated particles. Broken stone makes slightly stronger concrete than gravel, but as dense, and is an exception to the density rule given above.

Standard proportions for concrete (1 : 2 : 4 indicates 1 volume cement, 2 fine, and 3 vol coarse aggregate). For small work proportions may be selected follows: RICH MIXTURE, 1 : 1.5 : 3; for columns or other parts subjected to h stresses or requiring to be completely watertight. STANDARD MIXTURE, 2 : 4; for reinforced floors, beams and columns, arches, reinforced engine or chine foundations subject to vibrations, tanks, sewers, conduits or other tertight work. MEDIUM MIXTURE, 1 : 3.5 : 5; for ordinary machine founda- ns, retaining walls, abutments, piers, thin foundation walls, building walls, linary floors, sidewalks and sewers with heavy walls. LEAN MIXTURE, 1 : 3 : 6; unimportant work in masses, for heavy walls, for large foundations support- a stationary load, and for backing for stone masonry.

On larger or important work the proportions are determined by measuring the voids, ng 10% excess of cr uired to fill the same voids, and the same amount

of mortar in excess of that required to fill the voids in the stone; or better, by trying various mixtures to determine how much cement and sand will give the smallest volume (greatest density) for a given volume of stone. This will be the strongest possible concrete from the material used.

Table 5. Working Stresses for Concrete

Based on compressive strengths, etc, of Joint Committee of Eng Societies; to be used in absence of better data

Portland cement concrete			Columns			Bending		Diagonal tension and shear				Bond

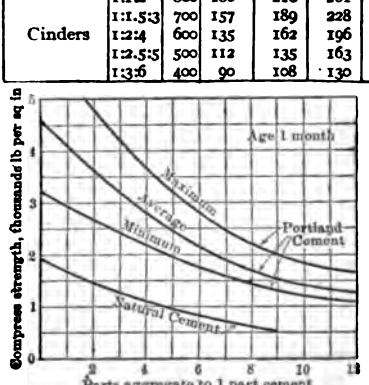

Fig 12. Compressive Strength of Concretes

Tensile strength of concrete, which is low and subject to great variation with slight changes in details of making, is generally neglected in design. For a 1 : 2 : 4 mix, it varies from 300 to 300 lb per sq in. for 1 : 3 : 6, from 100 to 175. Shearing strength is difficult to determine, but it is probably about 0.5 the compressive strength. Modulus of elasticity is also variable, the material not usually showing true elastic behavior. For working loads, it varies from 2 500 000 to 3 500 000 lb per sq in, depending on mixture and age.

Quantities of materials required for 1 cu yd concrete with various

centages of voids may be found by Fuller's rule for the approx amounts of ient, sand and broken stone in 1 cu yd of aver broken-stone concrete: 11 ided by sum of the parts equals number of bbls of cement. Multiply by the number of parts of sand and by the cu ft in 1 bbl cement (3.8 aver) divide by 27. This equals the cu yd of sand required. Similarly for the ken stone.

xample. 1 : 3 : 5 cement concrete. $11 \div 9 = 1.22$ bbl cement per cu yd. $1.22 \times 3 \div 27 = 0.51$ cu yd sand and $1.22 \times 3.8 \times 5 \div 27 = 0.84$ cu yd broken stone.

lixing and depositing. Cement is measured by counting the bags. Sand l stone are best measured by a bottomless box, the size of which is based on ıg an even number of bags per batch.

. 2-bag batch (about 0.5 cu yd) is convenient for hand work and 1 cu yd should be the t. In hand work, the sand and cement should be well mixed dry, spread in a layer the stone placed on top. Water is then put the stone, and the whole turned at least 3 es. Machine mixing gives better results, if amount of water is properly controlled. If , the concrete must be well rammed in layers ut 6 in thick, but in thin walls a wet mixture sed, simply requiring churning with a spade or k to loosen air bubbles and work it into all corners of the forms. Concrete should be tected from too rapid drying, and kept moist il thoroughly set. It may be placed under ter by means of metal pipes, the concrete being in at the upper end as fast as it goes out at the er end, thus preventing it from falling through water, which would wash out the cement. In ning old and new surfaces, care should be taken remove all dirt and laitance (scum which forms surface), and thoroughly to wet the surface of old work. In long walls, expansion joints uld be provided every 30 to 50 ft. Fig 13 shows common forms of joints. Concrete not injuriously affected by oils and acids, unless strong enough seriously to affect other materials. Salt or alkali water causes disintegration at the water line, due to unknown action, and sand containing alkali should not be used.

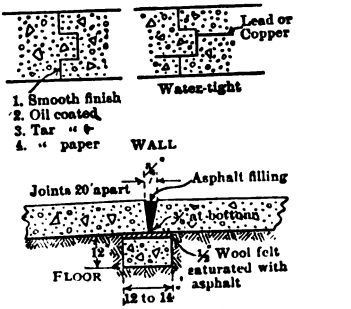

Fig 13. Concrete Joints

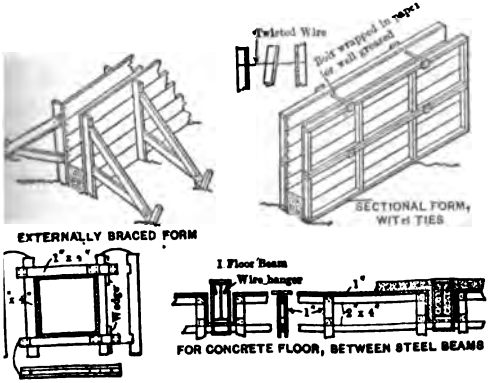

Fig 14. Forms for Concrete

Rates of work and costs. One man will mix, wheel 50 ft, level and ram, about 2.2 cu yd of concrete per 10-hr day. A gang of 15 men will handle as above an aver of about 33 cu yd, and 1 man will level and ram in 6-in layers about 11 cu yd per 10-hr day. Cost aries from $6 to $10 or more per yard, depending on labor and material costs, s well as the kind of work.

Forms for concrete are made of partly seasoned pine or spruce, planed on one side to give smooth surface and even thickness) and for best work tongued and grooved. The lagging is generally 1 in thick, but for heavy work and where the forms are to be used several times 2 in is better. Studding is commonly of 2 by 4 in to 4 by 6 in, spaced 1.5 to 2 ft centers for 1-in lagging, and 4 to 5 ft for 2-in. Pressure due to concrete is about that of a liquid weighing 80 to 140 lb per cu ft, depending upon the amount of water used in mixing and rate of placing. Since forms cost 0.25 to 0.5 of the entire cost of the work, a concrete structure should be designed with a view to simplicity in the form work, a little extra concrete often being economical. Forms should be carefully designed and constructed, so as to be easily removed without injury to the structure or the forms themselves; this is done by making them in units, joined by cleats, the pressure from the concrete being taken up by transverse tie wires, which are left in the concrete, or by external braces and struts. Adhesion of concrete to the forms can be prevented by applying crude oil, soap or grease. Fig 14 shows typical forms. The time which must elapse before forms can safely be removed depends on weather conditions and how soon the structure will receive its load. Time under ordinary conditions: Walls in mass work, 1 to 3 days or until concrete will bear press of thumb without indenting; thin walls and columns, summer 2 days, cold weather 5 days, provided they carry no load; slabs, up to 7 ft span, beams and girders, summer 6 days, cold weather 2 weeks; long-span slabs and girders, summer 10 days, cold weather 3 weeks to 1 month; arches, small 1 week, large 1 month.

Aver cost of form work is 8 to 12¢ per sq ft of surface.

14. Reinforced Concrete (23)

Concrete, reinforced by steel bars, is not yet fully standardized. It is economical for permanent structures, not because of its strength (which averages less than 0.5 that of timber) or low first cost, but because of its great durability, requiring little or no maintenance charges. Reinforced concrete structures can be built for the most part by unskilled labor. Details of design should therefore be simple, completely worked out and detailed on the plans, and construction must be inspected and supervised by competent engineers. Failures have often occurred through neglect of these requirements.

In general, the steel in reinforced work takes the tensile stresses, the concrete takes the compression. Relative economy of the two materials can be shown as follows. Steel costs 60 to 70 times as much as concrete per unit volume. In tension, steel takes a working stress of 16 000 lb per sq in, while concrete is limited to 30 or 40 lb. Hence, for tension, steel is about 500 times as strong per unit, or for same cost about 7 times. In compression concrete takes say 600 lb per sq in, and steel is only 25 times as strong; hence for same cost, concrete is about 2.5 times as strong as steel.

Reinforcing bars are usually 0.25 to 1.5 in. The 0.75-in bar is known as BASE, there being no extra charge for this size or larger, in either rounds or squares, but smaller bars cost more per lb. Odd sixteenths are seldom used. Square bars are more used than rounds, due to the fact that DEFORMED BARS are generally desirable and most of these are square.

Beams. Formulas are based on Navier's hypothesis (23) and on perfect adhesion between the concrete and steel.

Working formulas only are given herewith, and a constant coeff of elasticity is assumed; also the tensile strength of the concrete is neglected, as the concrete in the lower side of a beam develops fine cracks at about the same stress that would cause failure in a plain beam (corresponding to about 3 000 lb per sq in in the steel), and, the steel being computed for 14 000 to 20 000 lb per sq in, the concrete is thus of no tensile value.

For beams under loadings of less than 3 000 lb per sq in in the steel, a straight-line variation is assumed, and the tensile strength of the concrete should be considered. For beams near the ultimate, parabolic variation appears to suit conditions best and the tensile strength of the concrete is neglected. The span of a concrete beam is taken as the distance center to center of bearings, but need not be greater than clear span plus depth of beam.

tandard notation. For convenience the complete notation is given herewith.

Rectangular beams and slabs

= unit tensile stress in steel, lb per sq in
= " compressive stress in concrete, lb per sq in
= modulus of elasticity of steel
= " " " " concrete
$= E_s \div E_c$
= area of steel, sq in
= effective depth of beam, top of beam to cent of grav of tensile steel
= breadth of beam, in
= thickness of concrete below tension steel for protection
= elongation of steel due to stress f_s
= compression of concrete due to stress f_c
= depth of neutral axis below top of beam, in
= ratio of x to d, or $x = kd$
= ratio of lever arm resisting couple to d
= steel ratio $= A_s \div bd$ = % of steel ÷ 100
M_c = resisting moment of concrete
M_s = " " " steel

T-Beams

b = width of flange, in
b' = " " stem, in
t = thickness of flange, in

Shear and bond

V = total shear, lb
v_s = unit aver shearing stress, lb per sq in
u = bond stress per unit surface area of bar, lb per sq in
o = circumference of perimeter of bar, in
Σo = sum of perimeters of all horiz bars
a_s = area of steel in stirrup, sq in
l' = grip or required length of bar or stirrup, in
i = diam of stirrup or bar, in

ctangular beam and slab formulas (Fig 15). From Navier's hypothesis and ke's law (Art 2), $f_s = nf_c(1 - k) \div k$ . . . . (1), and resisting moment of beam based orking strength of the steel $= M_s = f_s pbd\,(d - x \div 3) = C_s bd^2$ . . . . (2), where $f_s p\,(1 - k \div 3)$.

ring similarly on concrete, $M_c = f_c(1 - x \div 3)\,x \div 2$ bd^2 . . . . (3), e $C_c = f_c(1 - k \div 3)\,k \div 2$. If resistoment of a beam d from Eq 2 is ter than that Eq 3, the beam, ted to failure, will

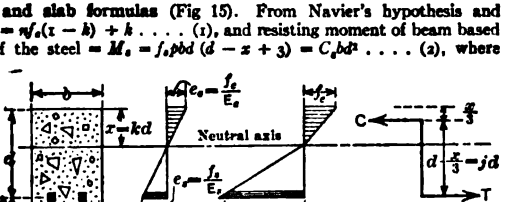

Fig 15. Stresses in Concrete Beams

y crushing of the concrete, and the beam is said to be OVER-REINFORCED. If conditions eversed, it fails by tension in the steel, and is UNDER-REINFORCED. If a beam has equal gth, figuring from either steel or concrete, it is a BALANCED BEAM. Thus, if n, f_s and f_c ixed from Eq 1, k is fixed, and $k = \sqrt{np\,(np + 2)} - np$ . . . . (4); hence, with k , p is fixed, and $C_s = C_c$, as would be required. M_s is then equal to M_c, and must = xternal moment M; hence, from Eq 2 or 3, $d = \sqrt{M \div Cb}$ . . . . (5), where C = e of C_s or C_c, when $C_s = C_c$. Value of d from Eq 5 is the BALANCED DEPTH, as it is the depth that will simultaneously insure full working values of f_c and f_s in a beam with d b fixed.

us, assuming $f_s = 650$, and $f_c = 16\,000$ lb per sq in and $n = 15$; from Eq 1, solving , $k = 1 \div [1 + (f_s \div nf_c)]$ . . . . (6); whence, $k = 0.378$. From Eq 4, which may ritten $p = k^2 \div [2n\,(1 - k)]$ . . . . (7), $p = 0.0077$, and from Eq 2 or 3, $C_s = C_c$ = 107.4. Table 6 gives values for other stresses.

or economy b should be small, since for equal strength, a deep narrow beam a smaller area than a wide shallow one. For proper design this can not be , and it is generally considered that b should not be less than 0.04 of the span e beam is not supported laterally, and that ordinarily b should be between nd 0.75 d. Using proper proportions for b and d, a beam of balanced depth adily designed, and closely approximates the most economical design.

the following examples, if the steel costs 70 times as much as the concrete, the be- cost in the ratio 166 : 208 : 172, the balanced-depth beam being cheapest.

Table 6. Constants for Balanced Beams

(Values of p, k, j, C and S for beams of balanced depth)

f_s	f_c	For $n = 12$			C		S, ft-lb

In getting A_s, two formulas are used. By definition $A_s = pbd$ . . . . (8), also, from F[illegible] $A_s = M + (f_s jd)$ . . . . (9). Eq 8 applies only if balanced depth is used, whereas E[illegible] gives sufficiently close results for other depths, and is used instead of Eq 8. Table 6 gi[illegible] values of the constant $S = f_s j + 12$, which may be used in formula Eq 9 with M in ft-[illegible] thus, $A_s = M + Sd$.

Example 1. Using same values of f_c, f_s and n as above, design a balanced beam f[illegible] load of 1 000 lb per lin ft, span 10 ft. (Load is taken to include wt of beam itself; [illegible] narily, a dead load must be assumed for the beam, and a tentative design made, whi[illegible] modified if the resulting wt of beam does not check the assumed wt.) For this beam, $M = wl^2 \div 8 = 13\,000$ ft-lb. From Table 6, $C = 107.4$ (in-lb units) or 8.95 (ft-lb u[illegible] hence, from Eq 5, $d = \sqrt{13\,000 \div 8.95\, b}$. Value of b is now assumed, so as to give s[illegible] factory proportions. By trial, if $b = 8$ in, $d = 13.5$ in, which is satisfactory. F[illegible] Table 6, $p = 0.0077$, and from Eq 8, $A_s = 0.0077 \times 8 \times 13.5 = 0.83$ sq in; or from table, $S = 1\,165$, and from Eq 9, $A_s = 13\,000 \div (1\,165 \times 13.5) = 0.83$ sq in. Table shows that several combinations of bars may be used to give this area; thus, 2 0.75-in rounds (area = 0.884) or 3 $\frac{5}{8}$-in rounds (area = 0.921).

n choosing the number and size of bars, there are several points. A minimum number esirable (2 for this beam), and if 2 are used the area is less than for 3, resulting in a ng in cost, and there is no extra charge ("size extra") for the 0.75 size, while there is for ⅞. But, if web reinforcement be necessary hereafter), it will be found to be desirable ave more than 2 bars. Also, there should certain MINIMUM SPACING BETWEEN BARS 16). In the above case, if 2 bars are used, am of 7 by 0.75 or 5.25-in is necessary; or 3 bars, 6.25; hence, either combination is factory from this standpoint. Fig 17 shows il of the beam using 2 bars. For slabs, the spacing permitted is 2.5 d.

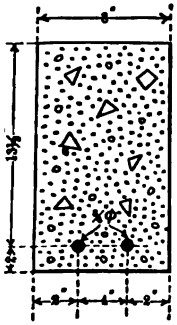
f = diam or thickness of bars

Fig 16. Spacing of Reinforcing Bars

nce d is the depth to center of steel, to get otal depth an amount e must be added for ection, etc. Common values of e are: For : when d is 3.25 in and under, e = 0.75 in; 1 d is between 3.25 and 4.75, e = 1 in; 1 d is 4.75 and over, e = 1.25 in. For ns and girders, the clear depth below steel, $-$ 0.5 i, must be 1 in when d is 10 in or under; 1.5 in when d is between 10 and 20 nd 2 in when d is over 20 in.

ample 2. Suppose a depth of 12 in is selected, that is, less than the balanced depth xample 1. The concrete will control and be stressed to full working strength, while the steel will be understressed. To keep f_s below 650, the beam must be over-reinforced. Thus, solving Eq 3, x = 6 in, or k = 0.5. From Eq 7, p = 0.0167 (against 0.0077 for balanced depth), and A_s = 0.0167 × 8 × 12 = 1.60 sq in. Also f_c will be 650 and f_s (from Eq 1) = only 9 750 lb per sq in.



: 17. Beam with 2 Reinforcing Bars

Example 3. Assuming 15 in for d, less steel may be used, and it will be stressed to full value, while the concrete will be understressed. The beam will be under-reinforced. Using S = 1 165, as for a balanced beam, Eq 9 gives a sufficiently close approximation for A_s, or 0.744 sq in. Hence p = 0.0062, and k from Eq 4 = 0.348. Since $j = d\,(1 - k \div 3)$ = 13.26 in, from Eq 9, f_s = 15 850, and from Eq 1, f_c = 570 lb per sq in.

Eq 5 and 9 are also used in designing slabs. EXAMPLE. Required a reinforced-concrete floor slab of balanced depth to carry 500 lb per sq ft on a 10-ft span. Take f_c = 500, f_s = 16 000 and n = 12. M = 6 250 lb for a strip 12 in wide. From Table 6, C = 5.17, hence since b = 12 from Eq 5, $d = \sqrt{6\,250 \div (5.17 \times 12)}$ = 10 in. Also, from Table 6, 1 212 and from Eq 9, A_s = 6 250 ÷ (1 212 × 10) = 0.43 sq in per lin ft of slab. sary spacing of bars of any size, to obtain this area, inches = 12 times area of 1 bar uired area A_s per lin ft. Thus 0.5-in round bars, 5-in centers, could be used, or ⅝ 8-in centers.

fe load. In using these formulas to compute safe load for a beam, first $p = A_s \div bd$, then compute k from Eq 4 and M_s and M_c from Eq 2, 3, using maller value.

mple. Find safe moment for a rectangular beam 8 in wide, 12 in deep to center of and having 0.96 sq in of steel. Take f_c = 650 and f_s = 16 000 lb per sq in, and n = 15. .01. From Eq 4, k = 0.418 and z = 5.0 in. From Eq 2, M_c = 159 000 in-lb. Eq 3, M_s = 134 300 in-lb. This beam is over-reinforced, and would fail by crushing concrete. It could carry 159 000 in-lb moment, and the stress in steel would not l 16 000, but the concrete stress would, hence M must not exceed 134 300, at which g f_s = 13 500 lb per sq in, from Eq 2. Test also for shear and bond.

agonal tension, shear and bond. Besides failing by crushing of the ete or breaking of the steel, a concrete beam may fail by diagonal tens

or by bond failure. Horiz and vert shear, modified by the fiber stress due to bending, produce max tensile stresses having direction shown by curved lines in Fig 18; hence, best position of reinforcing steel would be curved to follow these lines.

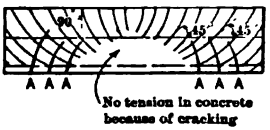


Fig 18

If horiz bars only are used, since concrete has little tensile strength, a beam may fail due to DIAGONAL TENSILE STRESS at ends, causing cracks A,A, as shown. As it is impracticable to compute diagonal tension, which is dependent on shear, shear is used as a measure of the diagonal tension in experiments and design. To prevent failure in this way 3 methods are used (9):

1. Shear is kept below safe value. It is recommended (23), for 1 : 2 : 4 concrete (for other mixes see Table 5) having horiz bars only, that the max intensity of vertical shear v, which $= 8\,v_0 \div 7 = 8\,V \div 7\,bd$ . . . . (10), should not exceed 4c lb per sq in. In designing slabs, where it is impracticable to place web reinforcement such as required in methods 2 and 3, the depth d is increased to keep v within this value.

2. Horiz bars are bent up at ends, usually at 45°, to conform more or less to curve in Fig 18. If this is done, v may reach 60 lb per sq in. This method is sometimes used for beams. Compute distance from support to point where $v = 40$, and beyond which web reinforcement is required. Bend up one or more bars at 45° within this distance. Compute aver total vertical shear V for length of beam s, in which shear is to be taken by bent up bar. Concrete is assumed to take ½ this shear and stress in bar bent up at 45° is $0.54\,Vs \div d$ . . . . (11), which should not exceed safe stress for bar. Note that bar can not be bent up until no longer required for tension reinforcement in bending. Also the BOND STRESS in the remaining horiz bars should not exceed a safe value. The stress u will be greatest at support, and $u = 1.14\,V \div \Sigma o d$ . . . . (12). If this exceeds 80 for plain and 100 or 120 for deformed bars, more bars must be used, or the ends of bars must be hooked to prevent their pulling out, or the length of beam over the support must be increased to obtain a length of embedment, $l' = f_s i \div 4\,u$ . . . . (13).

3. Stirrups are used. If these are figured to take ⅔ the shear (concrete is assumed to take the other third as in method 2), and in addition horiz bars are bent up, v may reach 120 lb per sq in (23), which is the max limit.

Stirrups (Fig 19) should be securely fixed to horiz bars, and not over 6" apart. Design is illustrated by following example for a T-beam. Note that in T-beams the stem only is considered effective for shear; b' is used in Eq 10 for b and computations are made same as for rectangular beams.

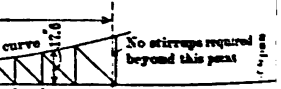

Fig 19. Common Forms of Stirrups

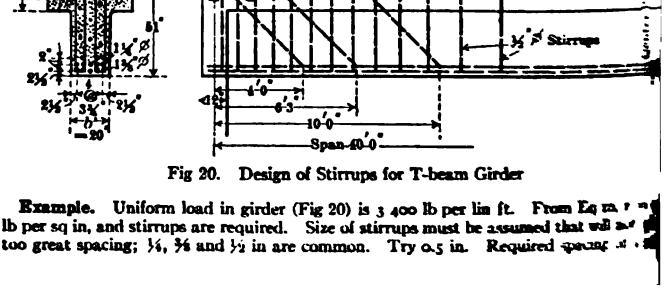

Fig 20. Design of Stirrups for T-beam Girder

Example. Uniform load in girder (Fig 20) is 3 400 lb per lin ft. From Eq 12, v = 60 lb per sq in, and stirrups are required. Size of stirrups must be assumed that will not allow too great spacing; ¼, ⅜ and ½ in are common. Try 0.5 in. Required spacing at end

tirrups (in) $= 1.31 f_s a_s d + V$ . . . . (14). If stirrup is bent as in cross-section in 0, $a_s = 4 \times 0.196$, and spacing at support, where $V = 68\,000$ lb, is 8.8 in. As the is uniform, at a point $l \div 8$, or 5 ft from the support, the spacing will be ½ of 8.8 or in, and at $l \div 4$, or 10 ft, $2 \times 8.8 = 17.6$ in (at $3\,l \div 8 = 4$ times). These values ıid off above the drawing of the beam, and to same scale (as in Fig 20). Draw a th curve through them. For a simply supported beam place first stirrups 0.5 minimum ng from center of support; for a continuous beam, same amount from edge. Draw al line in diagram, and from its intersection with the curve draw line at 45° locating stirrup, as shown. To find how many and where horiz bars may be bent up, from ı for one ⅜-in bar, u at the support would be 485 lb per sq in; hence, to keep this less 120, at least 4 or 5 bars must run to end of beam. All the bottom row, and center f second row, will run to end. Bend up the 1.25-in bars 2 at a time. Find distance support x_2, from formula $x_2 = l\left(1 - \sqrt{m_2 \div m}\right) + 2$ . . . . (15), where m = total of bars and m_2 = area to be bent up. Table 8 is computed from this formula, but ot be used as bars are not of same size. Thus, since area of 2 1.25-in bars is 2.554 and total area is 16 sq in, $x_2 = 12.2$ ft, etc, and bars are bent up, as shown in Fig 20, within these limits.

Table 8. Distance from Support for Bending up Horiz Bars, in decimals of span (uniformly loaded beams)

ample: span 20 ft; 6 bars in center; 2 can be bent up at 0.210×20 or 4.2 ft from support

beams. It is noted that the area of concrete below neutral axis in a rectilar beam is of no value against bending. If part of it is removed the re-g T-beam (Fig 20) will be stronger, as it is relieved of some dead load. e, as long as t exceeds x, the beam is essentially rectangular, and the formu-r rectangular beams are used. If t is less than x, use following formulas.

erring to Fig 21 it is seen that rectangular beam Eqs 1, 6, 9, hold equally well for T-. The compression carried by the small portion of the stem above neutral axis is y neglected. Practically $z = x - t/2) + (2x - t)]t + 3$ . . . . and can never exceed $t + 2$; approx, $M_s = f_s A_s[d - (t \div$ . . . (17). Actually $M_s =$ . . . . (9), where $jd = d -$ lso $M_s = [(2x - t)\,b[f_c jd] +$ . . (18), and $x = (2\,nA_s d +$ $(2\,nA_s + 2\,bt)$ . . . . (19).

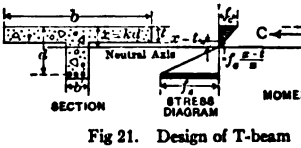

Fig 21. Design of T-beam

lesigning T-beams, a balanced depth is seldom used, but the proper proportions of re arrived at from other considerations, such as area required for shear, headroom, In general, proper proportions for stiffness require that b' shall be between ¼ and ½ so, where the stem forms part of a floor, the slab of thickness t being the flange.

economy the relation of b' and d should be such that $d = \sqrt{rM + f_s b'} + t + z \ldots$ where r = ratio of unit cost of steel to concrete, or 50 to 70. The value of t, where [illegible] forms part of a floor slab, is fixed, and b should not be taken greater than $8t +$ [illegible] distance c to c of T-beams, or over 0.25 the span. For independent T-beams, b should not exceed $3b'$, and t should not be less than $\frac{1}{2}d$. Three problems may arise.

Example 1. T-beam is part of a floor system; $t = 4.5$ in. Design stem for [illegible] of 92 700 ft-lb, max reaction = 16 800 lb. From Eq 11, remembering max allowable shear is 120 lb per sq in, the minimum area of stem $b'd$ for shear = 16 800 ÷ [illegible] = 160 sq in, or 8 by 18 would be satisfactory, as b' would be between $\frac{1}{3}$ and $\frac{1}{2}$ [illegible] required for proper proportions. But, from Eq 20, when $b' = 8$, it will be economical to make $d = 26.75$ in; but b' would then be too small, and if $b' = 10$, $d = 24$, so these proportions will be tried. From Eq 17, $A_s = 3.2$ sq in approx, which can be made [illegible] using several different combinations, as [illegible] and 2 0.75-in rounds, 2¾-in and 6 [illegible] rounds, etc. Using either combination, steel will have to be placed in 2 layers. [illegible] d = depth to center of gravity of steel, total depth must be determined as in Fig. [illegible] where $e = 1.5$ in. This design should be checked up by the exact formula, $8t + b' = 46$ in, and from (19) $z = $ [illegible] hence, this is a true T-beam and Eq 16 [illegible] to find $z = 1.82$ in; also from Eq 9, $f_s = 15\,400$ and from Eq 1, $f_c = 374$ lb per [illegible] which is satisfactory. Stirrups must also be provided.

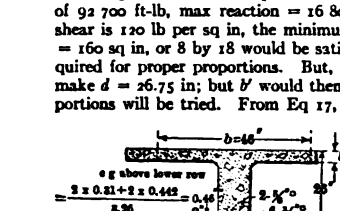

Fig 22. Design of T-beam

Example 2. Design an independent T-beam girder for 40-ft span, to carry live [illegible] of 3 000 lb and assumed dead load of 1 400 lb per lin ft. $M = wl^2 \div 8 =$ [illegible] in-lb. Max $V = 88$ 000 lb; hence, minimum area for shear = 838 sq in, or if [illegible] $d = 53$ or $b' = 18$, $d = 47$, etc. Selecting 18 by 47 as good proportions, and since [illegible] be at least $\frac{1}{2}d$, or say 16 in, this may be designed as a balanced T-beam. Then Eq 6, $k = 0.379$ and $x = 17.8$; hence, a true T-beam. From Eq 16, $z = 5.82$ in 2[illegible] 41.18. From Eq 9, $A_s = 15.80$ sq in, and solving Eq 18, $b = 44.8$ in, which is less [illegible] as required; hence design is satisfactory. To get 16 sq in, 7 1.25 and 5 1¼-in [illegible] would be required, and 3 rows of steel are necessary. To place this steel properly a stem is advisable; hence it is made 20-in instead of 18-in, and steel is placed as in [illegible] Dead load of this section is 1 480 lb per lin ft, which is not enough in excess of [illegible] sumption to require a redesign. END BEARING required is at least 88 000 × [illegible] 450) = 8.8 in. This assumes an allowable compression of 450 lb per sq in, and [illegible] the load by 100% to allow for unequal distribution over the bearing surface.

Example 3. Given T-beam forming part of floor; t, b', d and A_s being known; SAFE LOAD. Find b from data above, and x from Eq 19. If x is less than t, use [illegible] lar beam formulas; if greater, it is a true T-beam and z is found from Eq 16, giving [illegible] is computed from Eq 9 and M_s from Eq 18, and the smaller used. Also, test [illegible] shear and bond.

Columns. Long columns in concrete should be avoided, as variation in quality, almost certain to occur, seriously affect their strength. Usual [illegible] makes limiting area at least 64 sq in, length of plain columns, 12 and rein[illegible] 15 diams. Working loads are computed from tests of cylinders, columns considered as short blocks.

When reinforcement is used, the shortening of the concrete and embedded steel [illegible] the same, hence stress in steel will be n times that in concrete, or usually 8 to 10 [illegible] sq in. It is often held that cement is cheapest reinforcement for concrete [illegible] where space is not particularly valuable, and plain columns of rich mix are [illegible] economical. A 1 : 2 : 4 mix at least is always desirable. The outer 1.5 or 2 in of [illegible] is neglected in estimating strength of column and is considered as protection only. [illegible] able stresses for columns are given in Table 5.

Plain columns are designed for the necessary area, and the requisite amount of [illegible] terial for protection is added. Vertical steel rods, with spacing bands at intervals greatly to the reliability of the column.

einforced-concrete columns comprise: (*a*) those with vertical steel only, (*b*) hooped nns. Since the stress in steel must be n times that in concrete, the formula for longi- ıally-reinforced columns is $f = f_c[1 + (n - 1)\,p]$, where f = the aver allowable ɔression on net area, lb per sq in, f_c, n and p being as already given. Vertical rein- ment from 1 to 4% is used, 2 to 3% being usual economical limit. Vertical reinforcing, t straight and free from bends and symmetrically placed, is of doubtful value. It is to use wire ties, to resist outward flexure of rods, at intervals of not more than 18 in, ı times the rod diam. The compression rods should extend upward or downward into ɔlumn, lapping the reinforcement above or v enough to develop the stress in the rod by llowable unit for adhesion (13), or the ends of may be cut square and faced, and placed on of those above or below, with a short piece pe put over the end as a sleeve connection 23).

ldition of bands or spirals to columns having tudinal reinforcement has little effect upon strength up to the point at which they would vithout hooping. Columns reinforced with tal steel only are brittle, and fail suddenly ı yield point of the steel is reached, while use ops greatly increases reliability and ultimate gth. For this reason a smaller factor of y is used for hooped columns, than for col- ı with longitudinal steel only.

e longitudinal steel is figured as before, using formula. Total amount of hooping must be ss than 1% of volume of the column core en- d, clear spacing of hoops not over ⅙ the diam is core (preferably 0.1) or more than 2.5 in Hoops must be held firmly in place (Fig 23); ffect of hooping, which tends to prevent lat- flow of the concrete and is similar to the n of a pipe filled with concrete, decreases ly as ratio of length of column to diam of increases beyond 5, and it is best to limit hooped columns to 8 diams in length for the es of Table 5. A size for hooping steel can be selected, and the spacing found for d hoops from $S = 3.14\,d^2 + D$, where d = diam of wire. in (usual sizes, ½, ⅝, ¾, ⅞, nd 1 in), and D = diam of core, in. Footing detail for vertical reinforcing rods is im- nt, and, where length of embedment is insufficient to take all the stress, large rods d rest on suitable base plates in the foundation concrete; smaller rods may have a derable length bent outward into the footing. Bending stresses due to eccentric loads ateral forces must be met by increasing the section until the max stress (Art 6) does ceed the values of Table 5. Composite columns of structural steel, filled and covered concrete, form a class by themselves and can not be designed by the above formulas. *Bull* 56, Univ of Ill Expt Sta.)

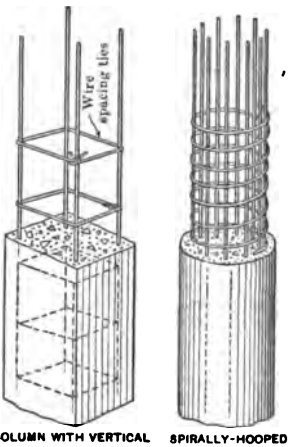

Fig 23. Reinforced-concrete Columns

15. Retaining Walls (9)

neral. Retaining walls are of masonry, sometimes laid dry in unimportant walls, ete or rubble concrete, or reinforced concrete. Principal forces acting are earth t and wt of the wall itself. In gravity walls these are the only forces to be con- d, but in reinforced walls the stability of the various parts must be investigated.

ravity walls (Fig 24). Considering 1 linear ft of wall, the earth thrust E be combined with wt of wall W, producing resultant R, and if R passes de toe of wall A the wall will overturn. R may be resolved into a vertical ɔnent V and horiz component H.

s generally required: (*a*) that R shall cut the base inside the third point; that is, ase will be eccentrically loaded. The formula of Art 6 applies, and can be reduced = $[1 \pm (6\,x \div l)]\,V \div l$ for a rectangular base 1 ft wide, where x = distance from of base (Fig 25), V = as above, and where + sign is used to obtain p_{max} and the —

sign to get p_{min}. When $x = o$, $p_{min} = p_{max} = V + l$; when R acts at third point $x = l + 6$ and $p_{min} = o$, while $p_{max} = 2V + l$; (*b*) that p_{max} shall not exceed the safe foundation pressure; (*c*) that H must not exceed the frictional resistance to sliding of the wall on its base. Resistance offered by the earth in front of the wall is neglected, and considered as simply adding to its safety. These requirements also apply to any horiz joint through the wall, but the base is generally the critical joint.

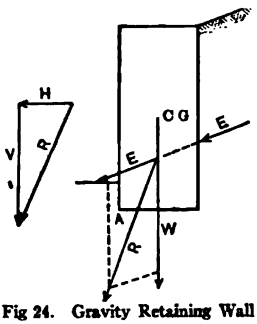

Fig 24. Gravity Retaining Wall

Requirement (*a*) is usually considered standard practice. It insures that there shall be no tension or uplift on the base, but it violates the general principle that center of base and center of press should coincide. In Art 7, safe foundation pressures are given for use in absence of better data. In selecting a safe value and designing the base so this value will not be exceeded as required in (*b*), the fact that the base press will not be uniformly distributed must be allowed for. With dry, compact foundation material, there is little danger of its soaking from the front to the rear of the base, and for walls foundations piles are generally necessary. Most retaining walls on earth settle forward slightly, and for this reason and for appearance the front is battered 0.5 to 3 in per ft. Foundation should be carried below frost line, usually 4 or 5 ft.

Stability against sliding is amply provided for in gravity walls if condition (*a*) is satisfied. Following are coeffs of friction of concrete on foundation materials: dry clay, 0.50 (or $\phi' = 45°$); wet or moist clay, 0.33 (18°); sand, 0.40 (22°); gravel 0.60 (31°); wood with grain, 0.60 (31°); wood across grain, 0.50 (45°). In reinforced retaining walls, sliding requires especial attention, due to their lighter wt, and projection of the base is often necessary (Fig 30, 31). To find the resisting value of this projection draw a line from its lowest point, making an angle ϕ with the horiz; take the wt of material above this line and multiply it by the coeff of friction of the earth.

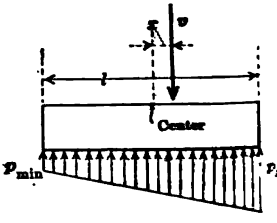

Fig 25. Maximum and Minimum Pressures

Earth pressure. No discussion of the formulas for earth press will be given (see 8). All writers agree that: (*a*) resultant thrust acts ⅓ up from base although experiments indicate that it varies from ⅓ to ½; (*b*) pressure varies directly with depth, or

$$E = Kwh^2 \div 2$$

where E = total press, lb, against a strip of wall 1 ft wide and h ft high, w = wt of filling, lb per cu ft, and K = a coeff, which is independent of the wt or depth of filling but depends on its angle of friction and other factors.

Theories vary in fixing a value of K. Best known formula is that of Rankine:

$$K = \cos\theta \frac{\cos\theta - \sqrt{\cos^2\theta - \cos^2\phi}}{\cos\theta + \sqrt{\cos^2\theta - \cos^2\phi}}$$

which gives value of K for a vertical wall with a fill sloping upward from its top at an angle θ, the material having a coeff of friction represented by angle ϕ. Authorities also differ as to the direction of earth thrust. Rankine's formula is theoretically correct for a granular, dry material, where the thrust acts parallel to surface of fill. If the back face of the wall is inclined, the press against a vertical plane is considered, and this is combined with the wt of the triangle of earth between this plane and the wall, to get the resultant pressure.

Fig 26 gives values of K for various values of ϕ and θ, between limits of $\theta = o$ and $\theta = \phi$. Values of ϕ and w are also given for some aver materials, but in this connection Rankine says: "The properties of earth with respect to adhesion and friction are so variable that the engineer should never trust to tables or to information obtained from books to any

in designing earthworks, when he has it in his power to obtain the necessary data er by observation of existing earthworks in the same stratum, or by experiments." ormula 2 is for active thrust. For passive thrust, or resistance to press of a bank of h, the signs must be changed from $\frac{-}{+}$ to $\frac{+}{-}$; whence $K' = \cos^2\theta + K$. For $\theta = 0$, K io of horiz to vertical press) = 1 for water, since water is frictionless or $\phi = 0$. For

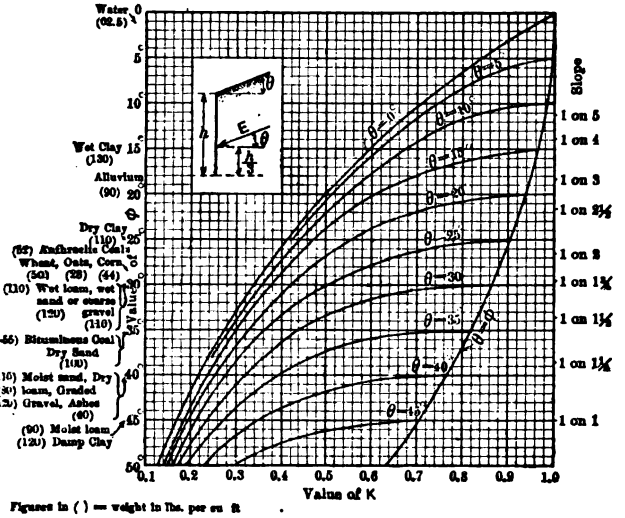

Fig 26. Diagram for Earth Pressure, Vertical Walls

· materials, K depends on the relative fluidity, and many designers use the equivalent r press. This assumes K times w, rather than K and w separately, a relation well h consideration, as it brings out clearly the value of proper DRAINAGE OF FILLING rial.

ɛ 27, *a*, *b*, *c*, shows action of earth thrust. In (*c*) the wall is subjected to a loaded fill h is to be reduced to equiv ft of earth h'. Thus, for a load of 500 lb per sq ft, $w = 100$ r cu ft, $h' = 5$ ft. For RR tracks, h' is usually taken from 6 to 8 ft.

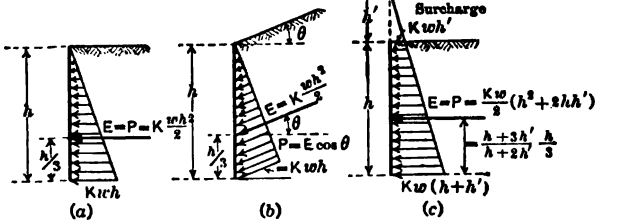

Fig 27. Earth Thrust on Retaining Walls

esign. For small walls, the base is sometimes made simply 0.45 or 0.6 of height, without computing thrust, pressure, etc. For high walls the dimen- s of the base are estimated as above, and then checked by finding the point

where the resultant cuts the base, the intensity of base press, and the stability against sliding. For these computations take a strip of wall 1 ft thick. Rectangular walls are seldom economical, and the trapezoidal form is used. A front batter is assumed of about 1 in per ft, and a top width of 18 to 24 in (largely a matter of judgment). A trial width of base is then taken, 0.45–0.6 h. This fixes the dimensions, and computations are made to see if any modification in base width is necessary.

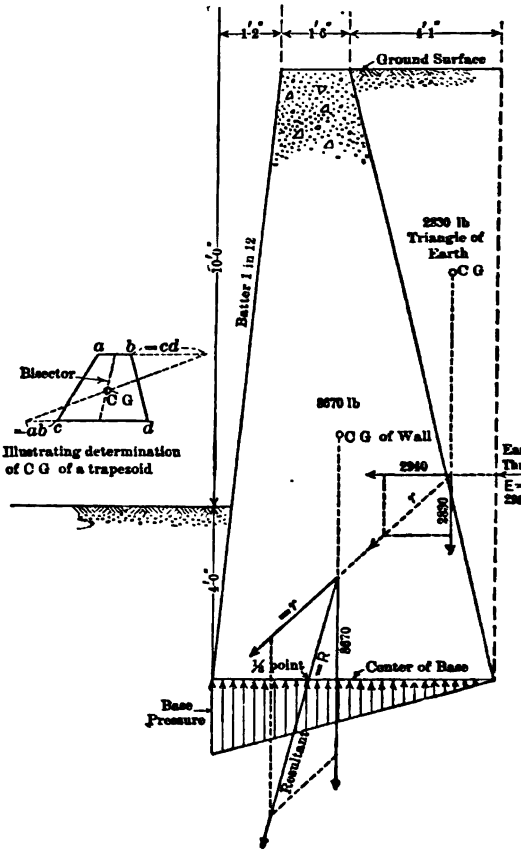

Fig 28. Graphical Design of Retaining Wall

Example. Design wall for 10 ft clear height, borix fill ($\theta = 0$), foundation, 4 ft deep. Assume $w = 100$ and wt of wall 150 lb per cu ft. Material gravel, $\phi = 33°$. Assume top width = 18 in. Take trial width of base $0.48\,h = 6.75$ ft, h being 0.3 (Fig 26). Wt of wall = 8 670 lb, wt of triangle of earth back of wall = 2 830 lb, also $E = 2\,940$ lb (Fig 27a). Fig 28 shows graphical construction, which proves this trial width of base is satisfactory. Max foundation press is 3 400 lb per sq ft, which is very low, and min = 0.

the final design, the back of the wall is usually stepped (Fig 29) to get better contact een the wall and earth, and resist tendency to overturn by friction of earth on earth, not earth on wall, which is less. Also the stepping, which is made to aver up to the sloping back of Fig 28, is convenient in designing sectional forms. The upper 3 ft are often left with a slope, forming a FROST BATTER, to relieve the wall of possible frost thrust. Expansion joints must be provided at intervals of 30 to 60 ft (Art 13). The variation from the trapezoidal form in Fig 29 results in a slight saving of material and smaller base press.

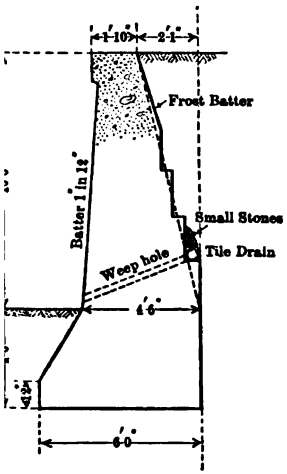

Fig 29. Stepped Retaining Wall

Reinforced-concrete retaining walls are of 3 types: cantilever, counterfort and cellular. Forms for the counterfort wall cost more than for cantilever, but the counterfort is more economical for heights 20 ft, while the cantilever is cheaper than the ity wall, except for very low walls. The cellular has been used where foundations are poor, and piles can not be used, and where wall must be built close to property line. (*Eng-Con*, May 10, 1911.)

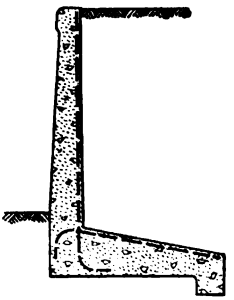

Fig 30. L-type Cantilever Retaining Wall

Cantilever wall of L-type (Fig 30) is required when the front face is on the property line, and the foundation can not extend beyond it. The base press in such walls is liable to be high, requiring the use of piles. Whenever possible, the T-type (Fig 31) is used, as it not only requires a smaller base and is therefore economical, but it gives smaller base press. The vertical stem should be placed at about the third point of the base.

DESIGN OF A CANTILEVER WALL (Fig 31). (*a*) Estimate is made of thickness of footing *ab*, which determines approx height of the vertical wall. Top width is assumed as 12 in, and base *ac* is found by Eq 5 (Art 14), considering the wall as a vertical cantilever subject to the earth thru

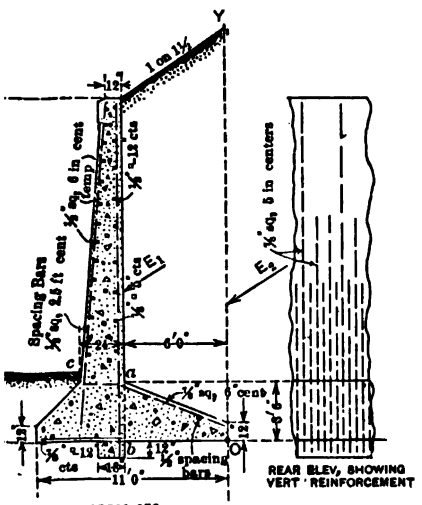

Fig 31. T-type Cantilever Retaining Wall

uniform, and solid rock should generally be required. For dams under 30 or 40 ft a trapezoidal section is economical, with the upstream face vertical or nearly so, a top width of 4 or 5 ft, and a height above extreme high water and waves of 2 or 3 ft. Base dimension is found as for retaining walls, with same 3 conditions for stability (Art 15). For low dams the base is determined by resultant passing inside middle third, but in high dams the allowable press limits the length of base or of a horiz joint through the dam. For rubble masonry 8 to 15 tons press per sq ft is permissible; for concrete, 8 to 10 tons. A force of 20 tons per lin ft of dam, acting at water level, is sometimes allowed for ice thrust. Rarely allowance has been made for possible upward water press on base due to seepage, but it seems unnecessary when the dam is properly bonded to the foundation and when a cut-off trench is made, as is usual (Fig 35). (Wegmann, "Design and Construction of Dams)

Buttress dams have advantages of construction and design that make them desirable and economical in certain locations.

Upstream face may be inclined as in timber dam (Fig 35*a*). In this way a uniform press is obtained at a reasonable cost, and such dams can be built on a footing less for the ordinary gravity type. Deck of the dam is constructed of arches spanning between the buttresses (*Eng News*, 27, 1915), or of a reinforced-concrete slab (*Sch of Mines Quart*, Apr, 1

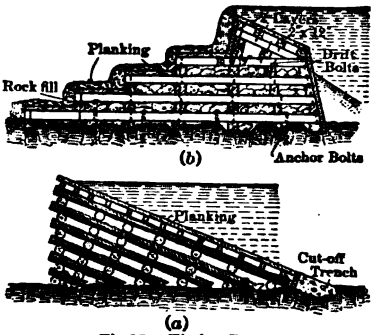

Fig 35. Timber Dams

Timber dams vary from cribwork brush dams to the more costly timber form.

Brush dams were first built as a makeshift, for diversion purposes where funds were lacking for more permanent construction, but several large size are still in use. The brush is tied in bundles with galvanized wire, deposited in layers with the butts downstream and weighted with stones and boulders. Log dams of solid timber are sometimes built, but timber cribs (Fig 35, *a* and *b*) are generally used for higher dams. They are often filled in with boulders, and sheathed with timber. Logs are notched at intersections and secured to each other by wood pins or drift bolts. These dams will last 20 to 50 years, or more if designed to be always wet, that is, the entire width should, if possible, be a spillway. Their max height is 60 or 70 ft.

Spillways, or waste weirs, must be able to pass safely flood flows, and are therefore designed with a liberal safety factor. When possible the spillway should be apart from main dam. Its length is usually fixed by flood width of the stream channel below, and probable depth of flow H can be found as in Sec 38, Art 10.

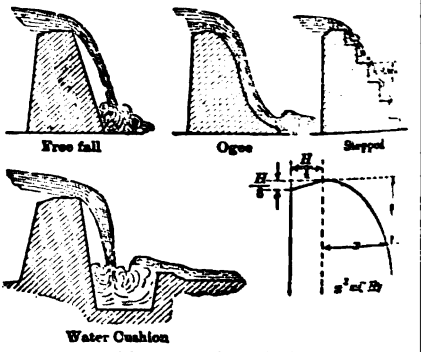

Fig 36. Spillways for Dams

Fig 36 shows types of spillways. When the stream bed is solid rock, if not over about 10 ft high, although a height of 20 ft has been used

/erse-curve section (an American type) the water leaves foot of dam with a direction rallel to stream bed, its velocity being destroyed by the backwater from below. Where backwater exists, and stream bed is of soft or loose material, an apron of concrete or ving is necessary to prevent scour d undermining. Upper part of spill- y curve is full enough to cause the erflowing water to adhere to the face the section; otherwise a partial vac- m might occur, also hurtful vibra- n. Fig 36 shows the curve used, *C* ng 1.6 for high, to 2.3 for low, dams. r gravity spillways, the section must heavy enough for stability. The ver curve is often made the reverse

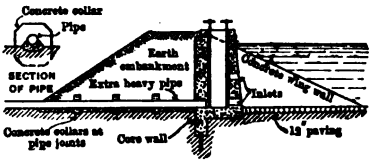

Fig 37. Outlet and Gates for Earth Dam

of the upper. The water cushion, often used by English engineers, is nature's method in many natural waterfalls and is also used with ogee and sloping sections. The depth is generally made about ⅓ the fall; the width, 3 or 4 times the depth.

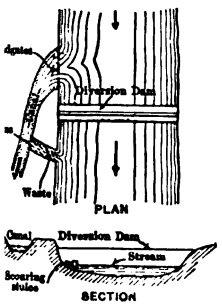

Fig 38. Headworks for Diversion Dam

Outlets and gates should be kept away from the dam if possible, so an accident may not endanger the main structure. For low earth dams the arrangement shown in Fig 37 can be used; for higher dams an inlet tower near toe of inner slope is preferable. This allows water to be drawn from different levels, which is desirable for water-supply works. Screens are provided to keep out large rubbish and fish. Area of screen openings should be 2 or 3 times the area of the pipe, and velocity of flow through the screen should be low. Finer screens should be put on portable frames, for ready removal and cleaning.

Gates are generally of the sluice-gate type, obtainable in circular or rectangular form up to 6 ft diam, or y 12 ft, and even larger. They move in tical guides set in the masonry, and are rated by hand wheels, cranks, or electric ors. A blow-off outlet for draining the rvoir is essential.

eepage around the outlet pipes of earth s may cause failure; all parts should be ssible for inspection and repair. Pipes bedded in concrete, with wide collars to ent direct flow of water (Fig 37). In more ly construction the pipe is in a special con- e or masonry tunnel.

leadworks for a dam for diverting water a canal are shown in Fig 38. A scouring e is essential, when much sediment is car- , which is deposited behind the dam due ecrease in velocity of stream at this point. ment can be kept from the canal by open- the scouring sluice during flood flows.

ulverts are small openings of a span of less 1 15 ft, generally built to carry a stream ugh an embankment. Area of waterway nds upon vol be carried, ch in turn ter, area, e, shape e basin 39a). qual to s-sectior of flood,

which can be found from high-water line. For small openings (up to 4 ft), one or C-I pipes can be used, with concrete end and wing walls to prevent scouring. Fig For larger sizes a concrete or masonry arch can be used.

ANALYSIS OF FRAMED STRUCTURES

17. Simple Frameworks. Loads

Truss is a framework designed to carry loads over larger spans that economical for beams. Fig 40 shows types for bridges; Fig 41, for roofs.

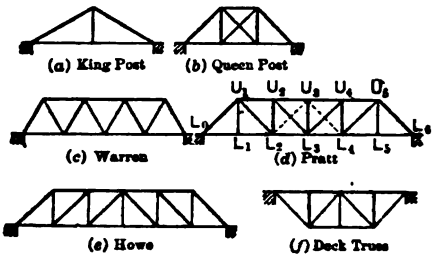

Fig 40. Typical Bridge Trusses

The loads from the roof or a bridge or covering of a truss are transferred to panel points (where members join) by the floor beams or purlins. Hence, true members do not carry loads but are only subjected to longitudinal stresses due to load. But, since their dead wt produces cross bending, the truss members are subjected to combined bending and direct stress. As this is unimportant except in bridge structures, it is customary to consider the dead wt of the truss as concentrated at panel points, and the truss members are designed simply for tension or compression, a − sign indicating compression and + tension.

In bridge work, if the floor system is supported at the panel points of the lower chord it is called a THROUGH TRUSS, if by upper chord a DECK TRUSS. The principle of division into triangles is also used for the bracing of towers and other structures.

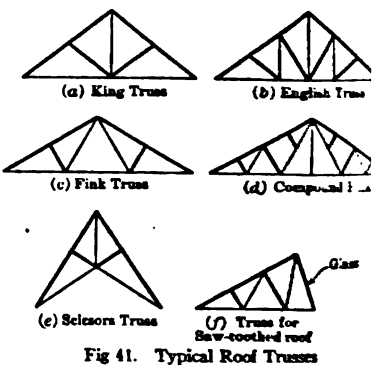

Fig 41. Typical Roof Trusses

In the following analysis only simple trusses will be considered. Structures containing REDUNDANT MEMBERS and other special forms can not be investigated by ordinary methods, as the stresses depend upon the relative elongation of the different members and are computed by the Theory of Least Work. Thus, the braced bent in Fig 40 would be STATICALLY INDETERMINATE, if both diagonals were counterbraced members capable of taking both tension and compression, that is were considered as acting simultaneously. Loading carried by any structure is of 2 kinds, dead load and live load.

Dead load is the wt of the structure itself, and can be closely determined. Table 9 is useful for computing dead loads. In designing, the dead wt must generally be estimated, and the computations revised if the estimate subsequently proves to be in error.

For ROOF TRUSSES the approx wts are found as follows. For wooden trusses, $W = 0.5\, al\,(1 + 0.15\, l)$, where W = total wt of 1 truss, lb, a = distance center to center of trusses

Fig 43. Loading for RR Bridge

Snow load must be considered in designing roofs in cold climates; 30 lb per sq ft for flat roofs, 20 lb for slopes over 20° and 10 lb (sleet) for roofs over 60° is generally ample. In some structures, temperature stresses must be considered.

Wind load must be allowed for in exposed structures, specifications requiring 30 to 40 lb horiz wind press per sq ft of vertical surface. For sloping roofs the wind press acting normal to the roof may be taken as follows, in lb per sq ft: slope 10°, 9.6 lb; 20°, 13.4; 30°, 26.5; 40°, 33.3; 50°, 38.1; 60° and over, 40 lb. Total press against curved surfaces as chimneys and tanks, is obtained by considering an equivalent flat area of same height and a width equal to ⅔ diam.

18. Methods of Truss Analysis

Algebraic method. Stresses in the members of simple trusses are easily found by applying the 3 laws of equilibrium for coplanar forces. $\Sigma V = 0$, $\Sigma H = 0$, and $\Sigma M = 0$ (Sec 36, Art 30–33). Two procedures are common, method of joints and method of moments, best shown by an example.

Fig 44 shows half of a Fink truss. The loadings P, P, etc, are determined by adding to the roof load, brought to the joints 1, 2, 3, etc, by the purlins, ½ the total wt of the truss which is supposed to be equally divided among the upper panel points. Vertical load 3.5 P, acting downward at A, can be neglected, as it is carried directly by the support. By the method of joints (Fig 44*a*) a section xy is passed, cutting members A 1 and A 5. Since ΣV and $\Sigma H = 0$, by the resolution of forces, and since $R = 3.5\ P$, the stress in A 1 $= 3.5\ P \div \sin\theta$, and stress in A 5 $= 3.5\ P \tan\theta$. By method of moments, a section is passed generally cutting 3 members, the stress in one of which is desired, and the formula $\Sigma M =$ is applied, taking moments about the point of intersection of the other 2 forces. Thus (Fig 44*b*), passing the section ys and taking moments about 4, $3.5\ P\frac{l}{2} - \frac{6}{8}\ Pl -$ (stress in 6–6′) $r = 0$, or stress in 6–6 $= Pl \div r$. The section passed may be either straight or curved. Thus (Fig 44*c*), passing the section mo and taking moments about 4, $(Pl \div r) +$ (stress in 2–7) $r + 2 = 0$, or stress in 2–7 $= Pl + 4\ r$. For the common rise of $l \div 8$ $(= r \div l)$, the stresses in the various members found by the continued application of P. The member 4–8 serves simply to support member 6–6′ at center and is not essential part of the truss and figures as carrying 0 stress. It actually carries 0 wt of 6–6′.

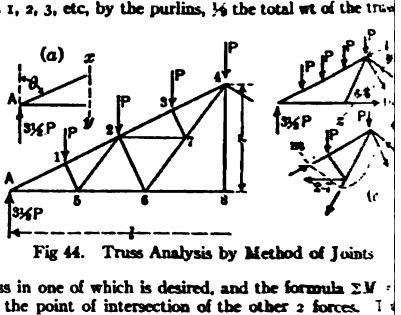

Fig 44. Truss Analysis by Method of Joints

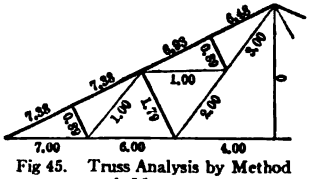

Fig 45. Truss Analysis by Method of Moments

In applying the method of moments to some structures, as the braced bent in g 46, members AC and FD must be prolonged to intersection at O, outside the ıss, and moments taken out O.

Thus, for the wind load own, reactions are equal d may be found by mo- nts about A or F. (Diag- al members are supposed be in tension, and the shed members are not ting stress for the loading own.) To get stress in E, take a section through S, AE, EF (Fig 46a). Tak- ; moments about O, $P_1b - P_2(a + b) - AEs' = 0$, ring stress in AE. To get ess in DE, take section rough DE, BE and BA ig 46b), and moments out B; thus $P_1a - DEy = 0$, giving DE. To get BE, te same section (Fig 46c) d taking moments about $BE \cdot (a + b) - P_1b - P_2(a + b) = 0$, giving BE.

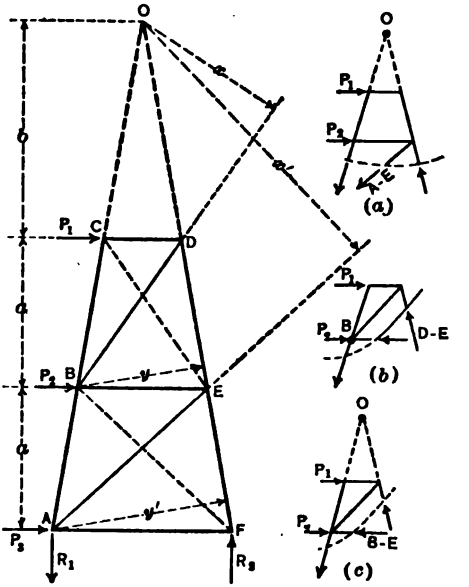

Fig 46. Analysis of a Braced Bent

Graphical method. ıis is often easier and orter than the algebraic ethod, due chiefly to e Bow system of nota- n. There are 2 dia- ams; one a TRUSS DIA- AM, showing lines of action of the forces in connection with the structure elf, and the other simply a FORCE POLYGON. Reactions in many cases are termined graphically, but it may be simpler to obtain them algebraically by ethod of moments (see above).

Thus, take a simple kingpost truss (Fig 47a), carrying a concentrated load at its center. llowing Bow's notation, the spaces between the lines of action of any 2 adjacent forces on the diagram, or the space within any triangle the sides of which are lines of action of any forces, are marked by capital letters. Employing a right-hand system of reading, indicated by the curved arrow, the reaction at 1 is called AB, the concentrated load CA, the member 1–2 is BD, etc. Referring to the force diagram (Fig 47b), the reactions are evidently equal to 0.5 the center concentration. Starting at any point, the line ab is laid off

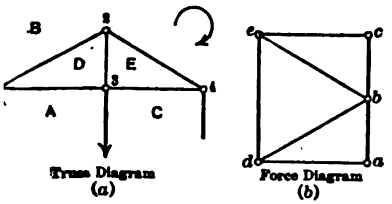

Fig 47. Graphical Method of Truss Analysis

ward from a, representing to scale the left reaction in direction and magnitude. Line bd ben drawn parallel to BD, beginning at b, and line da parallel to DA, beginning at a; their rsection fixes point d. In a similar manner the diagram is completed, as shown. he lines in the force diagram are now scaled off, giving the stresses in different member kind of stress may also be determined as follows: Considering any panel point, say he truss diagram, the member 1–2 is read DB. Noting db in the force diagram, it

seen that the direction from d to b is toward panel point 2, and DB is therefore in compression. Or, at panel point 1, member 1–3 is read DA, and, as direction from d to a is toward right or away from 1, this member is in tension. Analysis of stresses in hoisting headframes by the graphical method is shown in Sec 12.

19. Analysis for Moving Loads

For a fixed system of concentrated loads the max reaction is easily found giving the max shear, and the max moment is then computed by finding the section at which the shear passes through zero (this usually occurs under one of the concentrations known as the critical wheel), the moment at that point being a max. It is usual in small beams to design simply for max moments and shears, and to use the same section throughout. For moving load it must be so placed, with reference to the span, as to produce the max shear or moment.

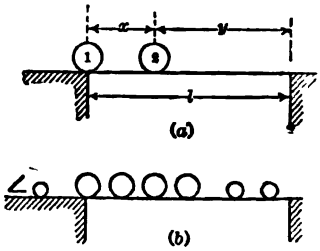

Fig 48. Analysis of Moving Loads

Max reaction or shear occurs at the support when the loads are as near as possible to that end of the span. Thus, in Fig 48a, the 2 loads must be moved so that wheel 1 will be a very small distance from the support, and reaction equals $P_1y + P_1$. For a locomotive (as in Fig 43) the first driver must be over the support (Fig 48b) and be considered as acting just to the right of the support.

Live load on truss bridges is transferred from the longitudinal stringers to transverse floor beams AB which carry it to the panel points (Fig 49a). Beams AB must therefore be designed to carry 2 concentrations, at x and y, equal to the max reaction from the longitudinal members framing in at these points. Sum of reactions from the 2 equal spans will be max when total load is max, and evenly divided between the spans. For a locomotive concentration this generally requires one of the middle drivers at x.

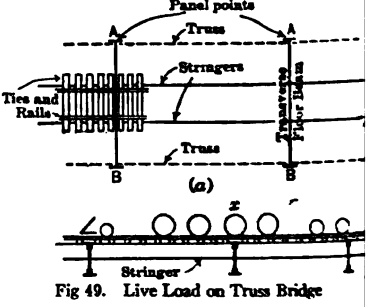

Fig 49. Live Load on Truss Bridge

Max moment at any section in a beam occurs when total load is divided in proportion to distances of this section from each end of beam.

Thus, max moment at section xy (Fig 50) will occur when sum of loads to left ($= W'$) is to sum of all loads ($= W$) as l' is to l. It is sufficiently accurate to determine M by this CRITERION for center of beam, and use it the max moment. But, the max moment will not be at the center, but at a point such that the distance between this point and the center of gravity of entire load is bisected by the center of span (Fig 51c). EXAMPLE. Take 2 equal loads of 1 000 lb, 4 ft apart, on span 10 ft. Max M at center is when 1 load is on either side of center, and equals 3 000 ft-lb (Fig 51a). Max possible moment is when load is placed as in Fig 51b. General formula for 2 equal loads: M occurs where shear $= 0$, when $x = (l + a) - (a + 4)$, and will equal

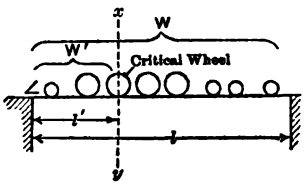

Fig 50. Max Moment on Truss (Approx)

$P + 2b)l - (a + 2)P$. This holds to $a = 0.586\,l$, after which max M is for 1 load at nter of span.

Stresses in truss members due to concentrated moving loads (Bib 11, 2, 13).

Referring to Fig 40*d*, for example, the dead load stresses, or those due to a fixed live ad, may be found by the methods of Art 18. But, if a moving live load is considered, must be moved to positions producing max tresses in each member. Thus, for max stress end post L_0U_1, the reaction of moving load L_0 must be a max, and max stress then quals this reaction + *cos* of angle $L_0U_1L_1$. $_1L_1$ is simply a hanger, carrying the max floor eam reaction at L_1.

For max live-load tensile stress in diagonal $_1L_2$, the load is advanced from right so as produce greatest shear in panel L_2L_3. The RITERION for this (see above) is that the total ad on bridge must equal n times the load on he panel in question. Stress in U_2L_2 will hen = shear + *cos* of angle $L_2U_2L_2$. Max hear in U_2L_2 = reaction at L_0 minus the oor-beam reaction at L_2. This condition of oading also gives the max stress in post U_2L_2, hich will equal the vertical component of $_2L_2$, or the shear. For a load advancing from ft, stress in U_2L_2 will be compression. This ember can be made as a counterbraced mem- er, capable of taking tension or compression, r to take tension only, and another tension ember U_3L_2, called a "counter," can be put , as shown by dotted lines.

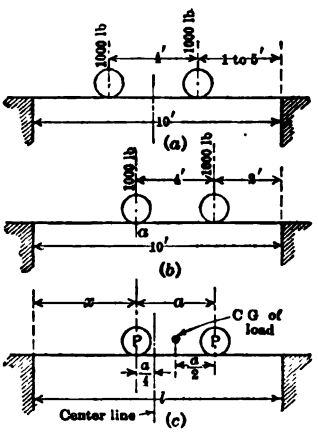

Fig 51. Max Moment in a Truss (Exact)

For max stress in a chord member, the load must be placed so as to produce the max oment in the chord. Criterion for this is the same as for max moment at any section of eam, or $W' : W$ as $n' : n$, where n = total panels in truss, n' = the number to left of ection, W = total load and W' = load to left of section. For U_2U_3, stress = $M \div$ height f truss, where M = reaction at L_0 times its lever arm minus floor beam reactions at L_1 nd L_2, each multiplied by their lever arms, the center of moments being taken at L_0 or ny point in the panel L_2L_3.

TIMBER STRUCTURES

20. Timber

Trade classification of woods: evergreens or soft woods (pines, spruce, emlock, cedar, cypress, fir); hard woods (oak, chestnut, hickory, ash, walnut, aple, birch, whitewood). Some "hard woods" are softer than the so-called ft woods.

Pine. Most useful of all woods. WHITE or northern white, from northern U S and anada: light, soft, not very strong, but easily worked; for interior finish, best grades for ttern making. WESTERN PINE covers timber sold as white pine, coming from Arizona Washington. IDAHO WHITE, from northern Idaho, western Montana and eastern ashington; not as strong as white pine, but resembles it and used for same purposes. OUTHERN YELLOW is of 2 principal kinds. Long-leaf is from southern coast, Virginia Texas, heavy, hard, strong, close-grained, tough; used for heavy framing and floors; n not be used in contact with ground, or built in solidly in masonry, as it decays rapidly ess dry, and dry-rots unless open to air. Short-leaf or Carolina is used as substi- r long-leaf. Variable in quality, the short-leaf being inferior. RED or NORWAY P ed for all construction purposes, is light, hard, coarse-grained. DOUGLAS FIR

OREGON PINE from north Pacific coast is the most valuable lumber of the Pacific region used for structural purposes instead of eastern hard pines; two kinds, red more valuable than yellow; imported to east when large size or length is required.

Spruce. BLACK or eastern from northern U S and Canada; light, soft, close-grained, tough in fiber; desirable for studs, joists and framing in buildings, also for piles, submerged cribs, etc, as it lasts well under water and resists destructive action of crustacea. WHITE: similar to black but not so common. WESTERN or SITKA, north Pacific coast. Giant spruce, soft, satiny, but inclined to be cross-grained; used for interior finish, fences, boats and cooperage.

Hemlock. EASTERN: brittle, splits easily, liable to be "shaky"; used in cheap, rough framing, as substitute for spruce, which it closely resembles in appearance. WESTERN said to be harder and superior in quality, but liable to shrink and warp.

Redwood. Giant tree and most valuable timber of California; used for same purposes in West as pine in East; soft and splinters easily; durable for fence posts, telegraph poles and RR ties (tie plates are used on ties to prevent wear).

Cedar. WHITE or arborvitæ: soft, fine-grained, durable, but lacks strength and toughness; used for tanks, shingles, boats, fencing, cooperage. RED: small size, very durable but brittle; strong, pungent odor; used for fence posts, shingles, etc.

Cypress, similar to cedar, used in northern U S for shingles, but in south as extensively as pine in north.

Oak. WHITE, from eastern U S: heavy, strong, hard, tough and close-grained; liable to check if not well seasoned; used where great strength is required in framing, boat building, etc. RED oak is similar, except in color.

Miscellaneous. HICKORY is hardest, toughest and strongest of all American woods; for tool handles. ASH, for interior work; is unfit for outside, as it decays rapidly. ELM, tough and very close-grained; used in wagons, cars, boats, barrel-staves.

Structure and sawing. The mature, compact inner layers are called HEARTWOOD; the outer 0.25 to 3 or 4 in being SAPWOOD, soft, open, and full of sap which hastens decay. Bark should always be removed. The fibers of the tree are in circular layers separated by ANNUAL RINGS, which are interrupted by radial cells communicating with the pith at center and the sapwood, and known as medullary rays.

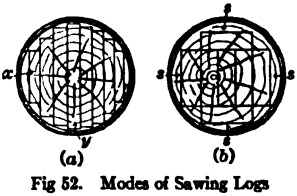

Fig 52. Modes of Sawing Logs

Fig 52 shows modes of sawing common lumber from a log: (*a*) for plank of uniform thickness; (*b*) for joists, etc, of same thickness and width. The part of log section from which lumber comes is of great importance. Thus, in (*a*) piece *x* is liable to warp or curl, due to unequal length of fibers on 2 sides, and if used in flooring is liable to splinter off. *y*, the best cut, is said to be RIFT-SAWED or comb-grained; makes best and most durable flooring. *sss* are SLABS. QUARTER SAWING, in plane of medullary rays, gives handsome finish.

Commercial sizes. FLOORING embraces 4, 5 and 6 quarter-in thicknesses, by 3 to 6 in wide, excluding 1.5 by 6. BOARDS, thicknesses under 1.5 in by over 6 in wide. PLANK, sizes from 1.5 to under 6 in thick, by 6 in and over wide. SCANTLING, sizes above 1.5 and under 6 in thick, and 2 to 6 in wide. DIMENSION TIMBER, sizes over 6 by 6 in. STEPPING, 1 to 2.5 in thick by 7 in and over in width. ROUGH-EDGE, or flitch, all sizes, 1 in thick and up by 8 in and up wide, sawed 2 sides only.

In U S, lengths increase by 2 ft; in Canada, by 1 ft. In dimension timber, sizes above stated may be obtained, but stock sizes vary in both dimensions by even inches; thus 6 by 6, 6 by 8, 8 by 8, etc. All sizes less than 1 in thick are counted as 1 in, in computing quantity. The unit is the BOARD FOOT, 12 by 12 by 1 in.

Finish. Rough timber and lumber, sawed to standard size, shall be not over 0.25 in scant. Thus, 2 by 6 may be 1.75 by 5.75 in. In small sizes, this greatly

reduces strength. Not more than 0.25 in is allowed for dressing each surface. The term $S\,1\,S\,1\,E$ indicates that 1 side and 1 edge are surfaced; $S\,4\,S$ means surfaced on 4 sides, etc. A 2 by 6 $S1\,S\,1\,E$ is usually worked to 1⅝ by 5½ in.

Shrinkage. Shrinkage is greatest tangentially to the fibers, that is, circumferential shrinkage; radial shrinkage is less. Flat-sawed lumber (Fig 52*a*, *x*) may crack and shrink 3 to 10% of width, thus opening spaces between boards or flooring, if not thoroughly seasoned. Longitudinal shrinkage is very small, generally less than 0.1%, which must be carefully considered in designing structures where settling is important; if possible, all timbers with horiz fibers should be eliminated from vertical supports. Effect of moisture is the reverse, and should also be considered.

Seasoning. Natural seasoning, used for lumber for construction purposes, requires 1 to 3 years, depending on kind of lumber.

Object is to remove moisture and dry up natural gums, thus guarding against shrinkage and decay. Lumber should be piled under cover, high and dry, thorough air circulation being allowed by placing strips between layers. WATER SEASONING consists in immersing timber in water about 2 weeks, to dissolve out soluble substances, and then air drying. Liable to make heartwood brittle or sapwood brashy. KILN-DRYING consists in placing lumber, usually only small sizes, in a kiln and exposing to a current of air at 100 to 200° F for 2 to 6 or 8 days. It generally produces inferior product, due to excessive drying of exterior and imperfect drying of interior.

Defects and inspection (5). Two things must be considered: quality and dimensions. Strongest and most durable timber comes from trees of slow growth, indicated by closeness of annular rings. Best timber comes from heartwood; should be straight in fiber, free from large or dead knots, flaws, shakes and blemishes. Dull, chalky appearance, or disagreeable odor, indicates decay and bad timber. Good timber is sonorous when struck.

In inspecting, timber is graded according to number, position and kind of defects visible in any piece. Thus, lumber is graded as first, second and third clear, or as No 1 or No 2, depending upon STANDARD DEFECTS shown, as pin and standard knots, sap stains, pitch pockets or streaks, checks, wanes or shakes, sap. The number of defects allowed depends upon kind of inspection: square-edge, merchantable, prime and clear inspection (5).

Decay. Life of timber depends on manner and time of felling, seasoning and working, and is always subject to attack by animal and vegetable life. Best time to cut timber is in winter and drier summer months, when cells are dormant and amount of sap small. Alternate wetting and drying, heat and confined air, fungi, insects, and worms are the chief agencies producing decay. Well-seasoned wood, in well-ventilated and uniform condition as to moisture, should never decay. Constant immersion weakens and softens, but does not decay.

Dry rot is due to excretion of ferments by a fungus which attacks cell walls, and breaks them down in the presence of moderate warmth, dampness and lack of ventilation. Occurs in wall pockets at ends of timbers and in cores of timber columns. WET ROT is caused by presence of moisture and warmth, which dissolves out cell walls in sapwood. COMMON ROT is due to improper seasoning without thorough ventilation, and is shown by yellow color at points of contact or yellow dust in checks and cracks. The most active worm is the TEREDO, or shipworm. It attacks timber in clear, unpolluted, sea water, from mean tide to ground level, and is especially prevalent on calcareous shores.

Preservation. CREOSOTING is the best preservative for timber, and is also effective against the teredo. It consists in impregnating with dead oil of coal tar or distillates from the wood tars (creosote). Timber is first placed in cylinders and sap vaporized by steam. After 0.5 to several hr, steam and sap are drawn off by a pump and the cylinder filled with oil, at about 160° F. When gage stands constant, showing no more oil is being absorbed, the surplus is drawn off. The entire treatment takes about 24 hr. Amount of oil varies, with kind of wood and seasoning, from 5 to 12 or 18 lb per cu ft for green and hard timber. Cost is from 10 to 20¢ per cu ft. BURNETTIZING consists in impregnation with $ZnCl_2$, in a similar manner as for creosoting. About 0.24 lb of $ZnCl_2$ is used per cu ft. Cost is about 3 to 8¢ per cu ft. Not suitable for timber exposed to moisture, as the $ZnCl_2$ will leach out. ZINC-TANNIN or Wellhouse process is same as Burnettizing, except that

Table 10. Working Unit Stresses for Structural Timber (lb per sq in)

Kind of timber	Bending			Shearing				Compression					
	Extreme fiber stress		Modulus of elasticity	Parallel to grain		Longitudinal shear in beams		Perpendicular to grain		Parallel to grain		For columns under 15 diam, working stress	Formula for working stress in columns over 15 diams long

White oak	5 700	1 100	1 150 000	840	210	270	110	920	450	3 500	1 300	980	1 300

Multiply the respective fiber stresses by $1 - (l + 60\,d)$

* Partially air-dried.

These unit stresses are for green timber, and are to be used without increasing live-load stresses for impact.

l = length, in. d = least side, in.

Note. Working unit stresses in this table are for RR bridges and trestles. For highway bridges and trestles, unit stresses may be increased 25%. For buildings, in which the timber is protected from the weather and practically from impact, unit stresses may be increased 50%. To compute deflection of a beam under long-continued loading, instead of that when the load is first applied, only 50% of the corresponding modulus of elasticity given in the table is to be employed.

For special information respecting varieties of Pacific Coast woods, with extensive tables giving moment of inertia, section modulus, wt per linear ft and total safe loads, see "Structural Timber Handbook," published in 1910 by The West Coast Lumberman's Association, 1016 White Building, Seattle, Wash.

a small quantity of glue is added to the Zn, and after completing the Zn treatment a solution of tannin is run in under pressure, which forms, with the glue, a leathery coating, closing the pores and preventing leaching out of the $ZnCl_2$. Several other methods and variations in the above methods are in use. KYANIZING, or impregnating with $HgCl_2$ and $CuSO_4$ is also used. Timber may be made incombustible by injecting Fe_2SO_4 and a solution of $CaSO_4$ or Na_2SO_4.

21. Columns and Beams

Tests and strength. Timber shows wide variation in strength depending on kind and age of tree, moisture content, size of test specimen, imperfections and knots.

Table 10 is from recent tests of selected timber, purchased in accordance with standard specifications of Am Ry Engs Assoc, and subjected to careful inspection. Unit stresses vary with class of construction, those in the table being for trestles and bridges. For other structures they may be increased as indicated, depending on character of loading, and freedom from deleterious weather conditions. No values are given for tension, as it seldom occurs without some bending, and the value for bending should be used. For weights see Table 9.

Table 11. Safe, Uniformly-distributed Load for Plank (lb per sq ft)

Based on fiber stress of 1 000 lb and longitudinal shearing stress of 100 lb per sq in. W = safe load, lb per sq ft = $192\ kd^2 \div l^2$ in bending and = $192\ sd \div l$ in shear, where l = depth of beam, in, l = span, in, k = allowable fiber stress and s = allowable shearing stress, both in lb per sq in.

Span, in	Thickness of plank, in							
	⅞	1	1⅛	1¼	2	3	4	6

60	.....	.....	.....	83	213	480	853	1 920
66	.....	.....	.....	.....	176	397	705	1 587
72	.....	.....	.....	.....	148	333	593	1 333

Table 11 for planking is based on a fiber stress of 1 000 lb, and an allowable longitudinal shearing stress of 100 lb per sq in. When ratio of span to depth of beam is less than the ratio of these stresses (10 : 1 in this case), the longitudinal shear determines the safe uniformly-distributed loading. For a single concentration at the center, the limit is twice this value. The limit is indicated by a heavy line, all values above the line being computed for shear and those below for bending. Table 12 is also based on fiber stress of 1 000 lb, but other table may be used for other stresses by changing these values in direct proportion. In using Table 12, the limiting minimum span must not be exceeded. Thus, for short, deep beams, s must not exceed the allowable value and will equal ⅔ the max vert shear, divided by cross-sectional area; or, for uniformly loaded beams or those loaded with symmetrical concentrations, max load in lb = ⅔ the cross-sectional area times the allowable longitudinal shear. Table 13 gives the unit stresses for columns for ratios of $l \div d$ effective length, in ÷ least side or diam, in) between 15 and 30.

Examples. Required safe uniform load for a 6 by 8-in spruce beam, spanning 4 ft. From Table 12, C = 42 667 ft-lb, which ÷ 4 = total safe load of 10 667 lb; or, dividing

Table 12. Coefficient of Strength (C) in Ft-Lb for Rectangular Beams

(Fiber stress, 1 000 lb per sq in) C in ft lb $= 8M = \frac{8}{12}kS$, where k = allowable fiber stress, lb per sq in, and S = section modulus, in

Depth, in	Thickness, in							
	1	2	3	4	6	8	10	12
1	111	222	333	4 444	667	889	1 111	1 333

6	4 000	8 000	12 000	16 000	24 000	32 000	40 000	48 000
8	7 111	14 222	21 333	28 444	42 667	56 889	71 111	85 333
10	11 111	22 222	33 333	44 444	66 667	88 889	111 111	133 333
12	16 000	32 000	48 000	64 000	96 000	128 000	160 000	192 000
14	21 778	43 556	65 333	87 111	130 667	174 222	217 778	261 333
16	28 444	56 889	85 333	113 778	170 667	227 556	284 444	341 333
18	36 000	64 000	108 000	144 000	216 000	288 000	360 000	432 000
20	44 444	88 889	133 333	177 778	266 667	355 556	444 444	533 333
22	53 778	107 556	161 333	215 111	322 667	430 222	537 778	645 333
24	64 000	128 000	192 000	256 000	384 000	512 000	640 000	768 000

again by 4, a safe uniform load of 2 667 lb per lin ft. But, the depth of this beam is $\frac{1}{16}$ the span, and the longitudinal shear will control; hence, total load may be only $\frac{1}{16} \times 6 \times 8 \times 100 = 6\,400$ lb, or 1 600 lb per lin ft.

Design a longleaf yellow-pine beam to carry concentrated center load of 10 000 lb, span 26 ft. $M = Pl \div 4 = 10\,000 \times 26 \div 4 - 65\,000$ ft-lb, and $C = 8M = 520\,000$. As the allowable stress for longleaf pine is 13 000 lb per sq in, Table 12 must be entered with $520\,000 \times 1\,000 \div 1\,300 = 400\,000$ as the required C, and a 12 × 18-in beam is found to give 432 000, which is more than ample for this load. (Similarly for Table 13.)

Table 13. Unit Working Stresses, Lb per Sq In, for Wood Columns and Struts (Carnegie)

$l \div d$	Longleaf pine or white oak 1 300 $(1 - l \div 60\,d)$	Douglas fir or western hemlock 1 200 $(1 - l \div 60\,d)$	Shortleaf pine, spruce, or bald cypress 1 100 $(1 - l \div 60\,d)$	White pine or tamarack 1 000 $(1 - l \div 60\,d)$	Red cedar or redwood 900 $(1 - l \div 60\,d)$	Norway pine 800 $(1 - l \div 60\,d)$

30	650	600	550	500	450	400

Deepened, built-up, compound or keyed beams. When no timber of required size is available, beams of this kind are used for temporary work and in some cases for permanent construction, though trussed beams are much lighter. If 2 beams are superposed, they have but twice the strength of one, neglecting friction between them. But, if they are

secured together (Fig 53) they act as a single stick of twice the depth, and are 4 times as strong as the single stick. Compound beam in Fig 53a is fastened by sheeting of planks at least ⅓ the width of timbers, with nails extending at least 0.5 their length into the main members; it has a strength of about 70% that of a solid beam of same dimensions. Beams with hardwood or metal keys (Fig 53b), preferably of a wedged type, are 75 to 80% as strong as solid beams. The keys transfer the horiz shear from one beam to the other, and are of such size that the safe end compression is not exceeded. Spacing must be determined for the safe horiz shearing stress. Keys should be about 2.5 times as wide as thick, and beam should be about 0.5.

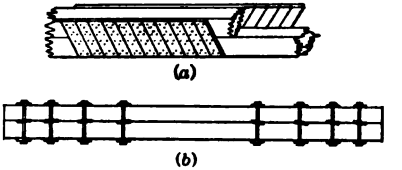

Fig 53. Compound or Keyed Beams

Design. *a.* Design cross-section of beam for bending = 1.25 to 1.33 times that computed (to allow for effic of 80 to 75%). *b.* Compute external vertical shear = V, at governing points. *c.* Compute intensity of horiz shear at neutral axis = $(3 + 2\ V) + bd$. *d.* Compute total horiz shear between end and point of zero shear (total horiz shear = aver intensity between any 2 points × b × distance between points). *e.* Select number of keys (usually 5) and divide (*d*) by this number, designing keys for bearing accordingly. *f.* Draw vertical shear diagram (horiz shear is proportional) and divide into number of equal areas (= number of keys) by vertical lines. Place keys in back of these lines. *g.* Check design for shear between keys. *h.* Design bolts as for tabled fish-plate joint.

Trussed beams are economical for spans over 20 ft, where headroom permits, or for shorter spans where saving in wt is an object.

King and queen-post trusses (Fig 54) are used. Usually the beam is a single unspliced piece, extending from end to end, with iron tie rods passing through oblique holes bored in the ends. If 2 pieces are used, they are separated with tie rods between.

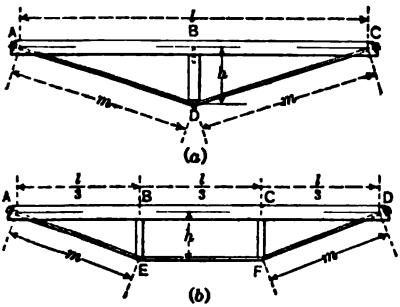

Fig 54. Trussed Beams

When the load is concentrated at the vertical struts, that is, for panel point loading, the stresses are found as in Art 17 and members designed accordingly. The only bending stress that occurs is due to wt of members themselves, which can be ignored except for long spans and small live loads. A uniformly-distributed load is carried partly by the beam and partly by truss action. The stresses can not be computed by ordinary means, but may be found as follows. In Fig 54*a*, king-post truss, W = total load, lb, on beam uniformly distributed. Compression in $BD = 5\ W + 8$; compression in $AB = 5\ Wl + 32\ h$; tension in $AD = 5\ Wm + 16\ h$. Design AD and BD for these stresses. Divide compression in AB by area of beam = bd, giving unit direct compression in AB; add to this the extreme fiber stress due to load acting on AB as a simple beam = $2.25\ Wl + bd^2$, and design AB so this total will not exceed allowable. All lengths are in ft, except b and d = breadth and depth of AB, in. When the truss is above the beam, AD will be in compression, BD and AB in tension, and the latter must be designed for max tension due to direct and bending stress, using same formulas. (Fig 54*b*) queen-post truss. Approximately, compression stress in BE and $CF = W + 3$; compression in AD = tension in $EF = Wl + 9\ h$; tension in AE and $FD = Wm + 3\ h$. Extreme fiber stress in AB, BC, or CD, acting as a beam, = $Wl + bd^2$.

A keg of nails or spikes weighs 100 lb. Table of boat spikes gives approx number in a keg of 200 lb.

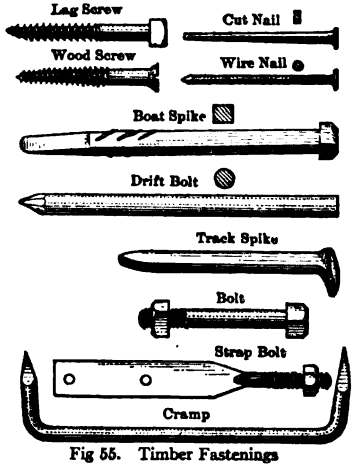

Fig 55. Timber Fastenings

22. Fastenings and Joints

Nails are classified as cut and wire. For lumber liable to split, cut nails are better than wire. They should be driven so that the tapering sides bear against the bent ends of the wood fiber, thus preventing splitting and acting like a wedge. Wire nails may be clinched or bent down; cut nails can not be bent. Table 14 gives common forms, designated in size by the "penny" system (d), probably originally the number of lb to 100 nails. Number per lb varies with different makers. Cost about 2 to 5¢ per lb. Nails should not be depended on for important joints, even in temporary structures. Large cut or wire nails are known as SPIKES. Boat or ship spikes are also made, forged from square bars with square head and chisel point. R R track spikes have a special head.

Drift bolts are long, steel pins, generally round (square are used), with or without heads. ¾ and ⅞-in diam are common sizes, but 1-in diam and up to 30 in long have been used. A hole should be bored 1/16 to ⅛ in less diam than bolt.

Treenails (wooden pins) are hard-wood pins, sometimes used as drift bolts, but commonly in mortise and tenon joints, etc. **DOWELS** are wood or iron pins extending into

but not through, 2 members, to connect them; they have neither point nor head. In heavy work, they are usually 0.75 to 2 in diam and 5 to 12 in long.

Screws comprise wood and lag screws. Wood screws are made to 6 in long, and some lengths in as many as 18 different diams. Thus, 3-in screws are from 6 to 26 gage (diam); 3.5-in, 8 to 26; 4-in, 8 to 30; and 4.5, 5, and 6-in, 12 to 30. Gage refers to special screw-gage, which is approx as follows: 6 = 0.14 in, 10 = 0.19, 15 = 0.26, 20 = 0.32, 25 = 0.39, and 30 = 0.45 in. For all large screws a hole should be bored less than diam of shank and about 0.5 its depth. For lag screws bore a hole equal in diam and length to shank, and then a smaller hole for about 0.5 length of thread. Lag screws have square or hexagonal heads, and are from 5/16 to 7/8-in diam for 3-in length; 5/16 to 1-in for 3 1/2 to 6-in length: 7/16 to 1 for 6.5 to 9-in; 0.5 to 1 for 10 to 12-in. Lengths vary by 0.5 in up to 8 in.

Bolts have round, square or hexagon heads, and are either rough or finished, rough being used for woodwork. Where used to prevent sliding of one member over another, the hole should be bored with a diam of 1/16 in less than the bolt, to give a close driving fit. Bolts have diam differing by 1/16 or 1/8-in. Where subject to vibration, lock nuts are used, or a nail is driven alongside the nut, or the thread may be "burred" to prevent nut working loose. (See Sec 41, Table 22.)

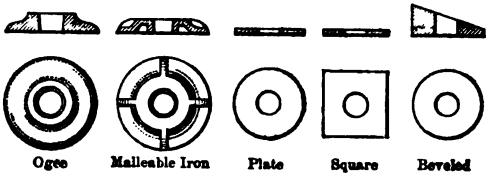

Fig 56. Washers

Washers (Fig 56) are important in timber work, to provide sufficient bearing area so that compression on surface of the timber may not exceed a safe value. They are of C I, steel or W I, and malleable iron. Common C-I washer is the Ogee (marked O G) form. Special washers can be cast when the number required warrants it. Steel and W-I washers are cut from plate, and are often too small and thin properly to distribute the bearing load. They should be about 4 times the diam of the bolt and 0.5 as thick.

Table 15. C-I Ogee Washers (dimensions, in)

Diam of bolt	Diam of washer	Thick-ness	Wt of 100	Bearing area	Diam of bolt	Diam of washer	Thick-ness	Wt of 100	Bearing area
3/8	1 1/2	5/16	8.5	1.57	1	4	7/8	180	11 57
1/4	2	3/8	22	2.83	1	4	1	194	11 57
1/2	2 3/8	1/2	37.5	4.12	1 1/8	4 1/2	1	215	14 68
5/8	2 1/2	1/2	45	4.47	1 1/8	4 1/2	1 1/8	295	14 68
5/8	3	5/8	75	6.63	1 1/4	5	1 1/8	320	18.15
3/4	3	5/8	72	6.47	1 1/4	5 3/8	1 1/4	469	21 21
3/4	3 1/4	3/4	100	7.69	1 3/8	5 1/2	1 1/4	425	21.99
7/8	3 1/2	3/4	115	8.84	1 1/2	6	1 3/8	525	26.20
7/8	3 5/8	7/8	150	9.54	1 1/2	6	1 1/2	688	26.20

Anchor bolts have a thread cut at upper end to take a nut, lower end being embedded in the foundation. Neat cement grout has been shown to be best material for setting the bolt; if there is no vibration, plain rods may be used, proportioned for 15 000 lb per net section of bolt, or 100 to 150 lb per sq in of embedded surface of bolt. Embedment of about 20 diam is needed to develop full strength of bolt. For machine foundations, it is best to use a bolt with nut and large washer at lower end and build it into the concrete.

Resistance to pulling of nails and screws varies with character of wood, depth of penetration, and for screws with size of hole used. Cut nails have higher holding power than wire, and the safe load may be taken at 4d in yellow pine and 7d in oak, where d = penny number of nail, driven across grain, to depth of 0.4 length; for wire nails, 2.5 and 4d. If subject to shock, the resistance is very low. For wood screws the safe resistance of a No 20-gage screw is twice that for a nail of same length. Lag screws show an ultimate resistance varying from 400 for white pine to 1 400 or more lb per sq in for oak; area being

length (exclusive of point) times circumference of screw. Safe lateral resistance of nails is roughly twice the resistance to pulling.

Timber joints. (Fig 57, 58.) Butt joint is effective for compression members, the ends being secured by other connecting members or by fish plates. Notching is widely used, especially for cribs; sometimes called GAINING or "dapping" or "sizing" when used in heavy framing to allow for inequalities in dimensions of timbers. HALVING is common in frame building construction, to join sills and wall plates. MORTISE AND TENON is a favorite joint for strength and rigidity. For 10 to 12-in timbers treenails should be 1 to 1.5 in diam, with a taper of 1/8 to 1/4 in. Hole in tenon should be about 1/4 the length of tenon from shoulder, and slightly nearer the shoulder than that in mortise, so the pin will draw the timbers together. STEPPING is common in all kinds of framing. Metal straps are sometimes used in framing structures subject to shock. Metal plates are used in heavy construction, and for joints in structures like derricks, which are often taken down and set up again. Beam hangers and column caps are used in heavy floor construction. Lap joint is simple, but only used for connections in minor members, due to its eccentricity and consequent bending on pins, etc. Half-lap scarf is widely used for joining members carrying small stresses, as guard rails on bridges, sills in buildings. Oblique scarf has more than double the strength of the half lap. Both joints are often used with fish plates in tension and compression members subjected to bending. Tabled scarf with key will take some tension, and when the amount is known the tables are easily designed for shear. Fish-plate joints, with wood or steel plates, are effective for tension. Bolts should be brought to solid bearing, to prevent timbers from buckling and to exclude moisture. Safe bearing loads per lin in are for safe bearing of 1 000 and 100 lb per sq in respectively. For other unit stresses, safe loads are obtained by proportion. For bending, the bolt is computed as a restrained beam with fiber stress of 22 500 lb per sq in (Table 16).

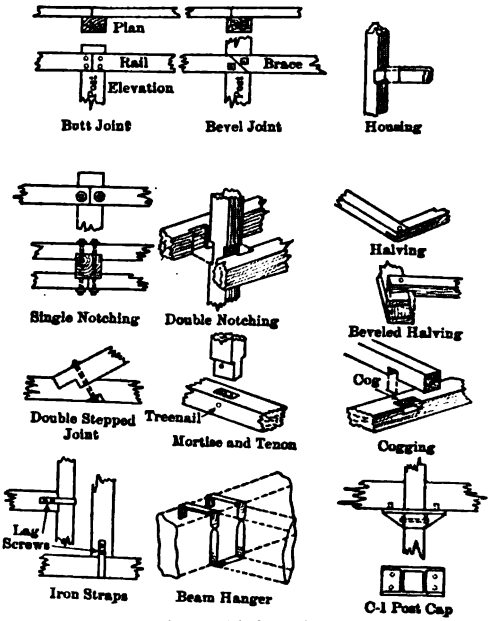

Fig 57. Timber Joints

Design of a plain fish-plate joint (Fig 58). A tension timber to be spliced is 2 by 8 in longleaf yellow pine. Allowable stress, 1 200 lb per sq in net section. 2 fish plates of same material will have to be 1 in thick each. Number and size of bolts are found from Table 16. Thus, try 0.75-in bolts. Safe end bearing for the timber is 1 400 lb per sq in. Hence, safe bearing load on 0.75-in bolt = 750 × 2 (= length of bearing) × 1 400 ÷ 1 000 = 2 100 lb. For bending, safe load = 3 720 lb; hence, bearing controls. Area of net section of member = 2 × (8 − 2 × 7/8) = 12.5 sq in, assuming that bolts are placed in pairs and holes are 1/8 in larger than bolt. Total tensile load = 12.5 × 1 200 = 15 000 lb, and number of 0.75-in bolts required = 15 000 ÷ 2 100 = 7. As an even number of

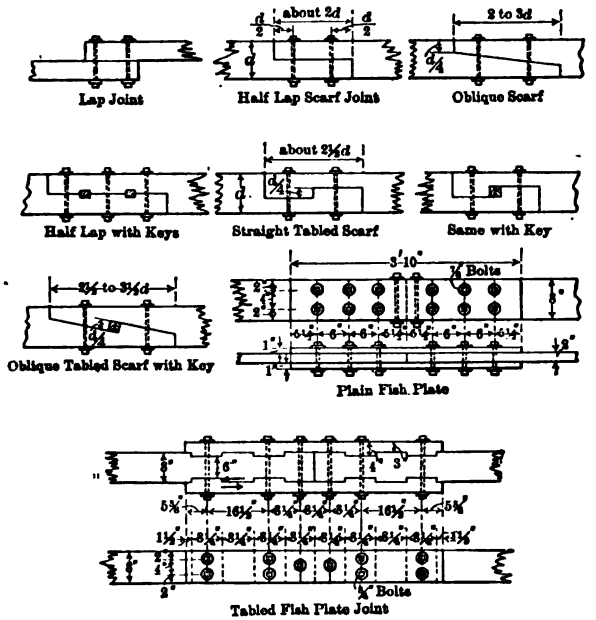

Fig 58. Lap and Scarf Joints

1	1 000	100	8 820	5 880	4 410	2 940	2 210	1 760
1⅛	1 125	113	12 580	8 390	6 290	4 190	3 140	2 510
1	1 250	125	17 250	11 500	8 640	5 750	4 300	3 450

olts makes a better design, 6 ⅞-in bolts will be used. Length of plate is determined by pacing of bolts, which tend to shear out a portion of the plate between planes tangent o top and bottom of bolt. Round bolts also tend to split the plates, so only 80% of safe hear with grain is used, or 80% of 150 lb per sq in = 120 (Table 10). Hence, distance etween bolt holes should be not less than 14 400 (= total load on net section for ⅞-in olts) ÷ [6 (= number of bolts) × 2 (= thickness of 2 fish plates) × 2 (double shear) × 120 (shearing stress)] = 5 in, or, adding 1 in for bolt hole, = 6 in c to c and 5.5 for ends. The TABLED FISH-PLATE JOINT in Fig 58 was designed for a load of 32 tons in longleaf yellow ine. The design is as follows, using for tension 1 800, for compression on end of grain 1 000, and shear along grain, 250 lb per sq in. a. Find areas required for tension, compression and shear, or 64 000 ÷ 1 800 = 35.6, 64 000 ÷ 2 000 = 32, and 64 000 ÷ 250

= 256 sq in, respectively. 4 tables are usually effective, and the shearing area of each would be 256 ÷ 4 = 64 sq in. In order that the length of table shall be not less than 4 its width (representing good proportions), the width of timber must be about 8 in, and the table a little over 8 in long to allow for bolt holes. Depth of tables must be 32 ÷ (4 × 8) = 1 in, to furnish necessary bearing area at their ends. Assuming ¾-in bolts and ⅞-in holes, the net depth of main member at tension must be 35.6 ÷ (8 − 2 × ⅞) = 5.7 in, making total depth of timber 8 + 5.7 = 13.7 in, or an 8 × 8 is needed. The fish plates, each taking 0.5 the total load and being of same material as main member, should be 0.5 as thick. Size of bolts may be roughly checked. Unlike the plain fish-plate joint, they transmit stress by tension. Thus the pull on fish plate is approx through its center (see arrows in cut), and this is transmitted to the main member by end bearing on the tables, approx at their centers. This causes a moment of (6 400 ÷ 4) × (1.5 + 0.5) = 32 000 in lb per table, tending to cause it to rotate about its edge. This is resisted by tension in the bolt and compression on face of table. The lever arm of this couple may be taken as 0.5 the length of table = 4 in, giving a pull on the bolt of 4 000 lb, assuming 2 bolts per table. A 0.75-in bolt is ample for this stress, using 15 000 lb per sq in, net section. The washers should have sufficient area for bearing, using 550 lb per sq in. A standard 3.25 C-I washer has an area of 7.69 sq in, and will transmit a total stress of 4 230 lb, which is OK. Bolts should be pulled up to a tight bearing.

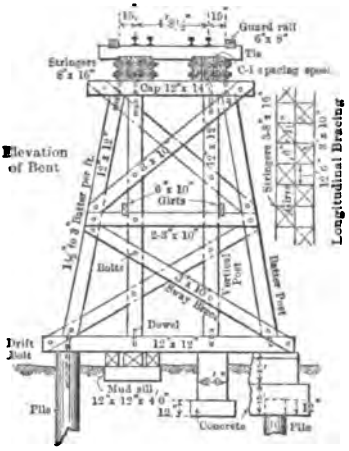

Fig 59. R R Trestle Bent

23. Trestles, Trusses and Bridges

Trestles consist of posts framed together to form bents, supporting a floor system of stringers, ties, and guard rails.

They are used for semi-permanent work, to avoid expenditure for permanent bridge or fill construction in the early days of a new R R, for making large fills, and in connection with mine dumps. Fig 59 shows a trestle bent, with different types of foundations used indicated. Where piles are used they may be long enough to form the posts (pile-bent), being sway-braced as for a framed bent. Bents are built in stories of 15 or more ft high. Fig 59 is a 2-story bent. Posts may be designed as columns, but are made larger than computations require to allow for decay. Stringers should be continuous over 2 spans, and are designed for bending stresses. Bents are spaced 12 to 16 ft apart, depending upon wt of loading. For light mine cars, the construction would be much lighter than that shown, which is for R R work.

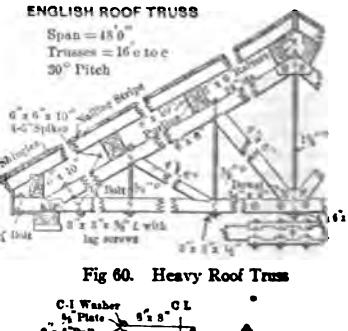

Fig 60. Heavy Roof Truss

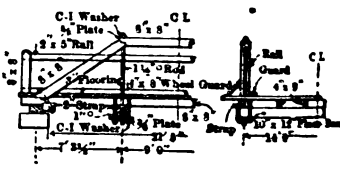

Fig 61. Small Highway Bridge

Roof truss of heavy design is shown in detail by Fig 60. Load from the rafters is rried to the panel points by the purlins; the stresses may be found (Art 17) for any sumed loading, and the members and details designed accordingly.

Small highway bridge, consisting of a queen truss with plank floor, is shown in Fig 61.

24. Frame Buildings

Framing is of 3 kinds: (*a*) MORTISE AND TENON FRAME, in which the members re mortised and pinned together. This requires a large amount of labor and r light buildings has been practically abandoned; (*b*) BALLOON FRAME, com- osed of lighter members, nailed together, and more quickly erected at lower ost; (*c*) COMBINATION FRAME, in which main iembers are mortised as in (*a*) and the stud- ing and bracing is nailed, used in the best odern construction.

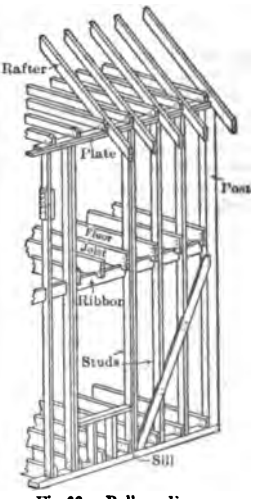

Fig 62. Balloon Frame

Fig 62 shows typical balloon frame for a 2-story ouse. Computations are rarely necessary. Sill is ually 4 by 6 in, halved at corners, on foundation alls or piers. Floor joists are of 2-in plank, 12 or in c to c; for joists over 12 in deep, 3-in thickness ould be used. Joists are braced laterally by cross idging, 1 row for 8 to 16-ft spans, and 2 for 18 to -ft spans, with 1" by 3-in bridging, or 2 by 3 for -in beams, nailed with 2 10d nails. Corner posts, ually 4 by 4 or 4 by 6-in, are set up and temporarily cured by "stay lath." Studs are held by a tempo- ry board nailed against inside. Studs are 2 by 4 . usually 16-in centers; they are spiked to the sills lower ends, and when practicable studs and joists e placed against and spiked to each other. Studs tend from the sill up to the plate, the second floor ists being supported on 1 by 7-in ledger boards, otched into the studs. The plate is usually of 2 2 by -in pieces. Joints in studs are made by nailing a sh plate on each side. Studding is doubled at indow and door openings. 1 by 6-in boards, otched into sill, post and studs, are used for corner aces. Rafters, 2 by 6 in, for lengths of 12 ft, 2 by to 18, 2 by 10 over 18 ft, are spaced 16 to 24 in cen- rs. Combination frame posts are usually 4 by 8 in, and the ledger board is replaced by 4 by 8-in girt, framed into the posts, the studding being separate for each story.

Partitions are usually of 2 by 4-in studding, spaced 12 to 16-in centers. In framing, should be remembered that timber shrinks but little endwise of the grain, and some- mes as much as 0.5 in per ft crosswise. Where settlement is to be avoided, all horiz iembers should be eliminated from vertical supports of the buildings. Partitions should st on the cap of the partition below when possible (not on the floor), or on a sole piece.

Covering. For cheap construction ship-lap is often placed vertically, with battens over e cracks. Beveled siding is commonly 6 in wide and laid 4.5 in to the weather. Molded ding (Novelty siding), is of ⅞-in boards, with ⅝-in lap. In best work, the frame is first overed with 1-in diagonal sheathing, which in turn is covered with building paper before e siding is placed. Shingles or corrugated sheets are also used for siding.

Shingle roof. Shingles vary from 16 to 24 in long, laid with 4.5 to 5.5 in (a little less an ½ the length) to weather. 4 bundles usually contain a "thousand" shingles, that , the equivalent of 1 M shingles 4 in wide, the widths varying from 3 to 14 in. Table 17 ives number of standard 4-in shingles for 100 sq ft of roof. Cost laid, $4.50 to $5 per quare (= 100 sq ft).

Tin roofing. There are 2 common sizes of tin, 14 by 20 in and 20 by 28 in, latter ' ' ost used. Thicknesses most used are I C (No 29 gage) and IX (No 27). Valu-

taken as 6 000 lb per sq in; for malleable iron, 15 000 to 20 000; for C I in compression, 20 000. Ultimate tensile strength of C I is from 16 000 to 30 000, depending on grade etc, some tests showing only 9 200, others up to 46 450; malleable iron averages 43 000. Compression tests show 44 500 to 215 000 lb per sq in, general aver being about 80 000.

Working stresses. CAST IRON is generally used for parts requiring no computation, or for compression members transmitting 10 to 15 000 lb per sq in. Tensile stresses are 1 000 to 4 000, depending on character of load and design. Columns are hollow, of round or square section. The straight-line formula, p (lb per sq in) $= 30\,500 - 160\,l \div d$, where l = length and d = least diam or side, in, represents the aver ultimate strength, and a safety factor of 4 to 6 should be used.

Wrought iron is tough, ductile, malleable, and easily welded, but can not be tempered. Steel has superseded it for bridge and building construction.

It is sold as MERCHANT BAR for blacksmithing and working into wrought shapes. It is said to resist corrosion better than soft steel, which is often sold for it. It may be distinguished from steel by etching for 15 or 20 min (in 9 parts water, 3 H_2SO_4 and 1 HCl); fibers will show up plainly, while steel dissolves uniformly. Principal defects are rough edges, due to poor rolling, spilly or spongy places, caused by imperfect puddling, blisters and excess of slag. Good W I should bend 180° cold around a diam 1 to 2 times the thickness of the test piece; it should show an ultimate strength of at least 46 000 lb per sq in, elastic limit of 25 000, and an elongation in 8 in of at least 20%. Fracture should show fibrous structure, though it may be made to show a coarse crystalline fracture by notching a tension bar all around and breaking suddenly.

Aver W I will test as follows: ultimate strength, 50 000 lb; elastic limit, 30 000 lb; coeff of elasticity, 28 000 000; stretch in 8 in, 20%, reduction area, 30%. It has no true ultimate compresive strength or modulus of rupture, but continues to deflect or compress without breaking. Aver values are taken as 55 000 and 50 000 lb per sq in. Usual working stresses are: tension, 12 000; compression, 12 000; shear, 7 500; bending, 12 000; torsion, 4 000 lb per sq in.

Steel, with a chemical composition intermediate between C I and W I, is produced either by adding carbon to W I or partly removing it from C I. Here it may be divided into 3 classes: soft steel, below 0.15% C; medium, 0.15 to 0.3% C; hard, over 0.3 % C. Soft steel is good for boiler plate, or wherever high ductility is advantageous; medium grades are used for structural purposes; hard grades are valuable for axles, shafts, and service demanding good wearing surface.

Carbon is the controlling element in steel, though other elements affect its strength to a smaller degree. Increase of C decreases ductility and increases strength. H. G. Colbell proposed:

For acid open-hearth steel, $T = 40\,000 + 68\,000\,C + 100\,000\,P + 80\,000\,CM$; for basic open-hearth steel, $T = 38\,800 + 65\,000\,C + 100\,000\,P + 9\,000\,M + 40\,000\,(CM)$; where C = % carbon, P = phosphorus, M = manganese, and T = tensile strength, lb per sq in. Table 19 shows the properties of different grades of carbon steel. Aver shear =

r, untreated. *A* = Annealed. *OT* = Oil-tempered.

rength of medium steel is 50 000 lb per sq in. In compression, structural steel acts like I. In general, elastic limit and ultimate strength are same as for tension. Coeff of sticity varies little with the carbon content and averages 30 000 000 for tension and 000 000 in shear.

Specifications (Am Soc Test Materials, 1909) require that for bridge work steel must be ade by open-hearth process, for buildings either the Bessemer or open-hearth, and for ret steel or plates over 0.75 in thick (which are to be punched) the open-hearth. A riation of 4 000 lb per sq in in tensile strength is allowed for structural steel for bridges. r material over 0.75 in thick a deduction of 1% in percentage elongation in 8 in shall made for each increase of 1/8 in over 0.75; also, for material under 5/16 in, a deduction of 5 shall be made for each decrease of 1/16 in under 5/16. Bend-test specimens are usually by 0.5 in section; $d = 3t$, etc, indicates bending around a diam 3 times thickness of bar. least 1 tension and 1 bend test are required from each melt, and if material differs 3/8 in more in thickness, separate tests are made from both thickest and thinnest metal rolled. Variation in cross-sec or wt of 2.5% from that specified is allowed, except for plates dered by wt. If these are over 12.5 lb per sq ft, a 2.5% variation is allowed, if under 100 wide, and 5% if over; for plates over 12.5 lb and under 75 in wide 2.5% is allowed; be- een 75 and 100 in, 3% below and 5% above; over 100 in, 3% below and 10% above. hen ordered by gage, thickness of plate shall not be over 0.01 in less than that ordered.

Inspection and defects comprise: mill inspection, inspection of rolled steel, and shop spection. In mill inspection steel ingots are examined to discover such defects as seg- gation, pipes and cracks, and blow holes; the first being generally found in upper part ingot, due to gathering together of certain chemical constituents, and the others due to o rapid cooling of outside of ingot. Good steel should show a bluish grey color on frac- re, with uniform grain, slight luster and silky appearance. In inspecting rolled steel, e chief points are the size and freedom from pipes, stars, pits, laps, seams, etc, caused by ove-mentioned defects in the ingot, and the failure to discard a sufficient portion of top ingot, where they generally occur, to assure sound metal. Shop inspection is equally portant, covering: straightening, marking and punching, assembling, reaming, riveting, cing, boring, finishing, and painting. Punch dies should be sharp and not over 1/16 in ater diam than the punch. Drifting is allowable only to bring parts together, and ould not be permitted for enlarging or matching up rivet holes. Facing and boring ould be carefully done and at proper angle to axis of the piece.

Alloy steels. NICKEL is used as an alloy for steel for guns, armor plate, and in some ructural work. Structural nickel steel has an elastic limit about 15% and ultimate rength about 25% higher than common structural steel, but nickel seems to decrease sistance to dynamic stresses. An alloy containing 36% nickel ("invar" steel) has a eff of expansion of about 4% that of steel; used for tapes and scientific instruments. HROME-NICKEL and CHROME-VANADIUM STEEL alloys have high elastic and ultimate rength, which, like most steel, may be greatly increased by tempering, at a sacrifice, how- er, of ductility (elongation and reduction of area). They are used in automobile con- ruction, machine parts, locomotive forgings, shafts, axles, etc. Manganese steel con- ining from 6 to 12% manganese is very tough and malleable and is used for frogs and vitches, crusher rolls and teeth for steam-shovel dippers. TUNGSTEN STEEL is used for ols for cutting metal and some varieties will cut when red hot.

26. Tables and Specifications

Standard rolled shapes. Following tables give the elements of the sections common use. Most of those listed may be termed STANDARD, in the sense at they are gen- rally kept ready or quick shipment the steel com- anies' ware- ouses. Beams re designated by epth and wt per t. Thus 15-in *I* 45 indicates an

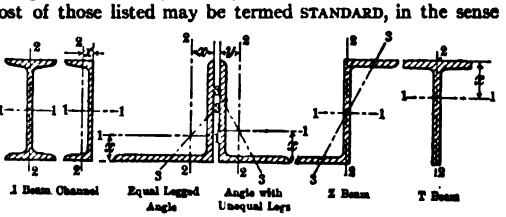

Fig 63. Standard Rolled Shapes

I-beam 15 in deep, weighing 45 lb per lin ft. Wt of rails is in lb per yd. Beams are cut in proper lengths and used singly, or combined by riveting with plates etc, as structural units.

Tables. (For completer tables see Bib 18, also Bethlehem Steel Co's Handbook.) Fig 63 shows cross-sec of the beams listed in Tables 20–25. Fig 64 shows other rolled sections, the H-beam being largely used for columns in building construction. The various factors given in the tables are used in computations and design. SECTION MODULUS is used in obtaining the fiber stress in beam (Art 4), or in selecting a beam for a given load. Coeff of strength (Art 4) gives a simple method of determining the safe load a beam will carry, as it equals 8 M, and for a uniform load = $\frac{8M}{l}$, where W = total load and l = span. Thus, the safe total uniform load on a 20-in I @ 65 lb for a 20-ft span, would be 1 247 600, the corresponding coeff, divided by 20 or 62 380 lb. Again, dividing by 20 gives a safe load of 3 119 lb per lin ft; or, dividing by 2, a safe concentrated center load of 31 190 lb. An approx rule, useful in absence of tables, is for standard I-beams the coeff of strength in ft ton = 0.5 the product of the depth times the wt per ft. Thus, for a 20-in I @ 65 C in ft-ton = about 650, or in ft-lb, about 1 300 000, against the actual value of 1 247 600.

Following is an outline of the Am Bridge Co's specifications. Unit stresses, lb per sq in:

Tension, net section, rolled steel 16 000

Direct compression, rolled steel and steel castings 16 000

Bending, on extreme fibers of rolled shapes, built sections, girders, and steel castings 16 000

Bending, on extreme fibers of pins	24 000
Shear on shop rivets and pins	12 000
Shear on bolts and field rivets	10 000
Shear (aver) on webs of plate girders and rolled beams, gross sec	10 000
Bearing press on shop rivets and pins	24 000
Bearing press on bolts and field rivets	20 000
Expansion rollers, press per lin in, not over 600 times diam of roller, in	
Axial compression on gross section of columns for $l + r$ up to 120 = 19 000 − 100 $l + r$, with a max of 13 000 (l = length of member, in, r = radius of gyration, in)

For structures carrying traveling machinery, as cranes, conveyors, etc., allowance is to be made for stresses resulting from such live load, to allow for impact.

Unsupported length of main compression members shall not exceed [illegible] gyration, or for secondary, 200. In getting cross-section of tension members [illegible] must be used, allowing for holes ⅛ in larger than rivets. In members subject to alternate stress, the greatest extreme fiber stress shall not exceed that given above. The unsupported length of beams and girders not to exceed 40 times width of flange.

Avoid adjustable members. No connection shall have less than 2 rivets. The ends of plates in girders shall not extend more than 8 times the thickness of the plate beyond the outermost row of rivets connecting them to plate. Minimum distance c. to c. of rivets not less than 3 diams of rivet, or preferably 3 in for ⅞ in rivets, 2½ for ¾, 2 for ⅝, 1¾ for ½. Max pitch in line of the stress, for members composed of plates and shapes, 6 in for ⅞ and ¾, 4½ for ⅝, and 4 for ½-in rivets. Where 2 or more plates are in contact, rivets to be not more than 12 in apart in either direction.

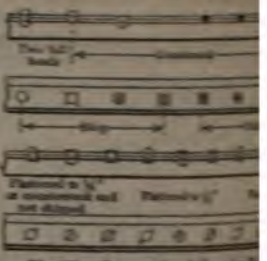

Fig 66. Conventional Signs for Rivets, Bolts, and Rivet Heads.

27. Rivets, Bolts, Connections

Rivets are of special steel (Art 25) and are computed for certain stresses (Art 26). They have a head already formed, and a [illegible] dependent on thickness of metal they are to go through.

SPLICE PLATES and their rivets are sometimes computed to transmit the entire ...en members, but the chief reliance is on the end bearing. SHOP RIVETING. ...f the total riveting as possible should be done in the shop, resulting in better

work and saving in cost. On small jobs, it may be economical to use bolts instead of rivets for connections. In BRIDGE WORK, pin connections are common, pins being calculated for shearing, bending, and bearing stresses, of the latter usually controlling. For bending, resisting moment = $frd^3 \div 32$, where d = diam, in; f = fiber stress, lb per sq in.

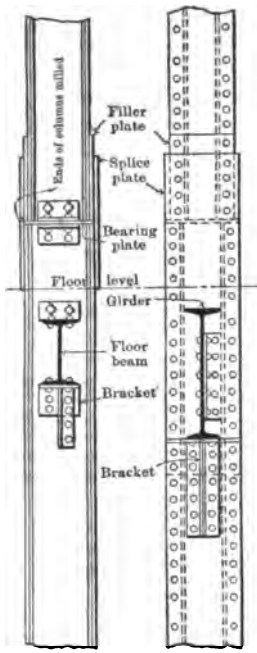

Fig 69. Connections for Plate and Channel Column

28. Columns and Girders

Columns may be of single, rolled sections, built up of plates, channels, and angles. The H-SECTION is widely used and saves in cost of fabrication. Design of a built-up column is simple, as shown below (see also Art 29).

Design a 45-ft latticed plate and angle column for a load of 250 000 lb (Fig 70). In general the unsupported length should not exceed 120 times the least radius of gyration r, or for secondary members, 200. Hence, smallest r for this column would be about $45 \times 12 \div 120$, or 4.5 in, and since, from type 10 in Fig 71, $r_x = 0.36\,h$, the plates should be at least $4.5 \div 0.36 = 12.5$ in. But better proportions require a width of $\frac{1}{15}$s to $\frac{1}{40}$ the length, or about 16 in, in which case r_x = about $16 \times 0.36 = 5.76$; using the formula $p = 19\,000 - 100\,l \div r$, $p = 9\,600$ lb per sq in, and necessary area = $250\,000 \div 9\,600 = 26.1$ sq in. Selection of plates and angles to make up this area is largely a matter of judgment. A plate should not be wider than 55 times its thickness, or angle legs longer than 9 times the thickness. Try 2 16 by 0.5-in plates and 4 3 by 3 by 0.5-in *Ls*. Total area = 27 sq in (Table 21). This design should be checked for axis $x - x$, and distance b determined so as to make r at least equal for axis $y - y$. Since moment of inertia (I) of a section about any axis = I about the axis through its cent grav + area times square of distance between axes, the value of I about $x - x$ is found as follows: For plates, $I = bh^3 \div 12 = 341.3$; for angles (Table 21) about own axis $I = 2.2 \times 4 = 8.8$ or plus $4 \times 2.75 \times (8 - 0.93)^2 = 550$, or total = 890.1; and, since $r = \sqrt{I \div A} = 5.75$, it checks closely with that used in determining p. From Fig 71, $r_y = 0.53\,b$, or $b = 5.75 \div 0.53 = 11$ in. Taking I about $y - y$ axis, this may be checked as before, and r is found to be satisfactory. Rivets for angles and plates in this design must be spaced not over 6 in, or 16 times the thickness of thinner plate. In this case 6 in controls, and 0.75-in rivets will be used. For about 1.5 times the width of column, or 2 ft at each end, rivets are pitched at 4 times their diam (= 3 in) to give extra strength where load is applied.

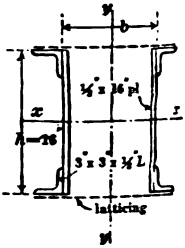

Fig 70. Latticed Column

Component parts of a built-up column must be rigidly connected and held in place, to maintain the radius of gyration r. This is done in columns of types 8, 9, 15, 16, etc (Fig 71), by means of solid plates or diaphragms. It is sometimes undesirable. Thus, for bridge posts, types 10, 13, 14 of Fig 71 are used, to make the entire section accessible for painting and connections. Upper chords are usually made with plate on top and open below (type 11). To maintain rigidity of open members single or double LATTICE BARS are usually applied to the main part of the column, with BATTEN PLATES to give greater rigidity at ends and intermediate connection points, or where latticing is interrupted (Fig 28, 29, 30).

Joint for a column shown in Fig 69. here columns rest masonry footings C-I base or steel se plate is used.

Girders. When ie bending moent is too large r a standard lled beam, a spe-al beam or girder ust be built up. irders are usually ade with flanges rmed by angles iveted back to ack, with cover lates to give re-uired flange area hen necessary, nd a web consist-ig of a plate PLATE GIRDER) or ı light construc-ion, latticing (LAT-ICED GIRDER).

In plate girder de-ign (19), the web is ssumed to resist all he shear and the anges the bending ıoment. Upper ange of a girder is ı compression and ower in tension, and

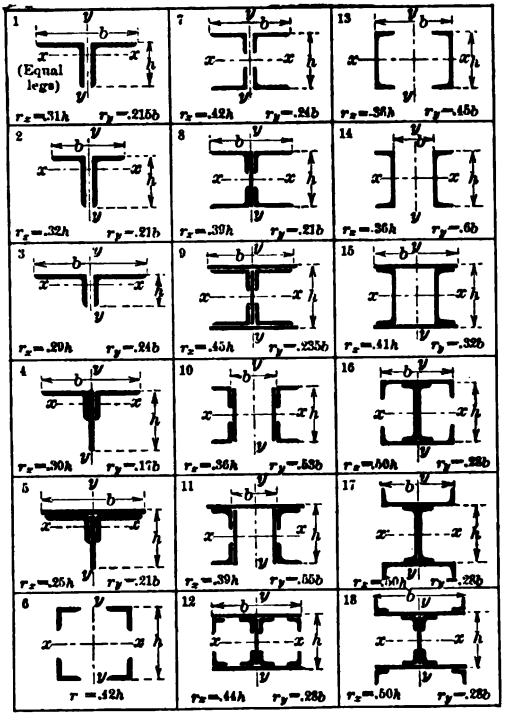

Fig 71. Approx Radii of Gyration of Column Sections

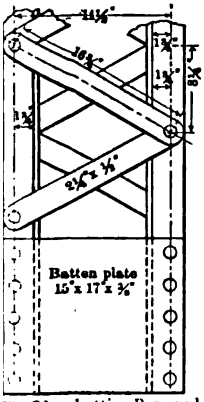

Fig 72. Lattice Bars and Batten Plate

resisting moment, in-lb, $= fdA$, where f = allowable unit stress, lb per sq in, d = EFFECTIVE DEPTH of girder, in, and A = net flange area, sq in. Since the web can resist a small amount of bending, allowance is often made for this by considering a fractional part (usually ⅙) of the web as equivalent to flange area and adding it to the net area of flange angles and cover plates. Only the tension flange is usually designed, the compression flange being made the same. Effective depth is distance between centers of gravity of upper and lower flange. It can only be obtained accurately by series of trials, and for small girders is often taken as equal to depth of web; it will generally be greater when cover plates are used. (For details of design of built-up girders, see Bib 19.)

29. Bridges and Buildings

Bridges. Various forms of trusses (Fig 40) are used to carry loads on spans too great for plate girders, or where there is insufficient headroom for a deck girder and a truss is economical.

No definite limiting span can be set for different types of bridge construction. For ordinary loads, roll-

can generally be used up to spans of about 20 ft, and plate girders up to spans of 120 ft and over under certain conditions, but the aver limit is about 50 or 60 ft. In U S, trusses of 150-ft span or less generally have riveted connections; trusses of larger span are usually connected. Riveted connections are stiffer, but harder to erect. (For details of design of small and large bridges, see Bib 19.)

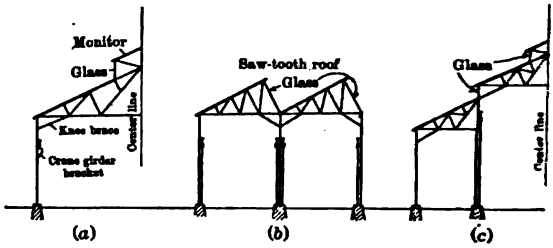

Fig 73. Forms of Steel Buildings

Buildings. Steel mill buildings are of 3 types: (*a*) steel truss and braced columns, covered with corrugated iron (Art 24), or thin concrete walls, supported by the steel frame; (*b*) same as above, except columns are braced by thin walls supporting masonry walls; (*c*) steel roof trusses, supported on masonry walls.

Fig 73 shows 3 common forms of construction. Saw-tooth roof is usually so placed that the glass has a northern exposure. Fig 74 shows the cross-sec of a building of type *a*, with wind force acting against it. Dead and snow-load stresses in the roof truss are computed as in Art 17, but the column, brace, and wind stresses depend largely on wind load and on condition of fixity of columns. Fig 74 illustrates conditions when columns are

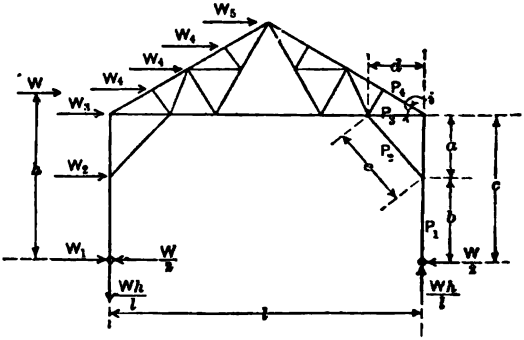

Fig 74. Distribution of Wind Pressures on Roof Truss

assumed as fixed at upper and hinged at lower end, which is usual assumption. Wind load is taken as acting at panel points, the individual loads being W_1, W_2, W_3, W_4, and W_5. The resultant W, acting at height h, is found by taking moments about the column base, the forces required for equilibrium being shown. In column P_1 the max moment producing bending is just below the knee brace, and $= Wb + 2$; the column must be designed (Art 6) to allow for this, in addition to direct load from truss. The shear above brace $= Wb + 2a$, and below brace $= W + 2$. The direct stress due to wind below the brace is $Wh + l$; above brace $= (Wc + 2d) - (Wh + l)$. In brace, $P_2 = Wcs + 2sd$. Member $P_4 = (Wc + 2d) - (Wh + l)\ cosec\ i$. Chord $P_3 = P_4 \cos i - Wb + 2a$. Stresses in other members of the truss are found by applying the forces P_2, P_3, and P_4 to the truss and methods of Art 18.

Fig 75 shows crane girders for carrying the rails for traveling cranes. If the girder is pported by a bracket as in (*a*), the resulting eccentric stress must be allowed for (Art 6). ith a wider column below the girder in (*b*), the connection with the aller upper section must be de- ned for the moment due to wind. aveling cranes are liable to produce ide thrust, usually taken as 0.05 the ing capacity of the crane acting on ch of the 4 wheels; 25% should also added to crane stresses for impact d vibration. (For details of monitor, ss construction, etc, see Bib 22.)

The design of a steel roof truss made in an entirely similar anner to the small bridge given ove. The purlins are either of nber, with wooden roofing as in g 60 (in which case a short ece of angle is used as a brace attach the timber purlin to e steel truss at the panel point), for a corrugated iron roof the rlins would be of steel, giving eproof construction.

16. Weights and Measures

(See also Circular No 47 of U S Bureau of Standards, on Units of Weights and Measures, issued July 1, 1914)

Avoirdupois Weight

ains	Drams	Ounces	Pounds	Hund'd-wt	Net tons	Gross tons
1	0.03657	0.002286	0.000143	0.00000127	0.00000007135	0.00000006371
34375	1	0.0625	0.003906	0.00003488	0.000001953	0.000001744
5	16	1	0.0625	0.00055804	0.0003125	0.00002790
000	256	16	1	0.0089286	0.0005	0.0004464
1 000	28 672	1 792	112	1	0.056	0 05
00 000	512 000	32 000	2 000	17.857	1	0.89286
80 000	573 440	35 840	2 240	20	1.12	1

lb avoir = 1.215278 lb troy. 1 net ton = 2 000 lb = 0.892857 gross ton.

Troy Weight

Grains	Pennyweight	Ounces	Pounds
1	0.041667	0.0020833	0.0001736
24	1	0.05	0.0041667
480	20	1	0.0833333
5 760	240	12	1

1 lb troy = 0.822857 lb avoir. 175 oz troy = 192 oz avoir.

Apothecaries' Weight

Grains	Scruples	Drams	Ounces	Pounds
1	0.05	0.016667	0.0020833	0.00017361
20	1	0.333333	0.0416667	0.0034722
60	3	1	0.125	0 0104167
480	24	8	1	0.0833333
5 760	288	96	12	1

The lb, oz, and gr are same as in troy wt. Avoir gr = troy gr = apothecaries' gr.

Density

1 Chin (catty)	"	596.816	"

20. Japanese Measures

van, = 3.75 kg or 8.2673336 lb avoir, is the unit of mass. It is divided 1 000 mommes, the momme into 10 funs, the fun into 10 rins, the rin into os, and the mo into 10 shis.

aku is the unit of length, equal to 10 ÷ 33 (0.30303) meter, or 0.99419 ft. It is decimally divided into sun, bu, rin, mo, and shi. Multiples

the shaku are: the ken = 6 shaku; the cho = 60 ken, and the ri = 36 cho = 12 960 shaku.

The shaku (land measure) = 0.00033 are (metric), or 0.9884217534 sq ft. 10 shaku = 1 go, 10 gos = 1 bu or tsubo, 30 bu = 1 sé, 10 sé = 1 tan, and 10 tan = 1 cho.

The shaku (capacity measure) = 0.01804 liter, or 0.0180616 U S liquid quarts. 10 shakus = 1 go, 10 gos = 1 sho, 10 shos = 1 to, and 10 tos = 1 koku (4.96 bushels).

Metric weights and measures are recognized as legal in accordance with the above equivalents.

21. Russian Measures

Funt, = 0.40951241 kg, or 0.90282028 lb avoir, is the basis of Russian weights. The funt is divided into 96 zolotniks or 32 loths, and the zolotnik is divided into 96 dolis; 40 funts = 1 pood.

Archine, = 28 in or 0.71120 meter, is the basis of length measure. The archine contains 16 verskops; 3 archines = 1 sagene and 500 sagenes = 1 verst.

Dessiatine, = 2 400 square saganes or 2.6997245 acres, is the unit for land measure.

Tchetvert, = 2.09908 hectoliters, or 5.95666 U S bushels, is the unit for dry measure. The tchetvert is divided into 8 tchetveriks, and the tchetverik into 8 garnets. 12 tchetverts = 1 last.

Vedro, = 12.2993285 liters, or 3.249119 U S gal, is used for liquids.

22. Spanish-American Measures

Arroba = 25.4 lb av = ¼ quintál = 11.42 kg (also, in Spain, 1 arroba = cántara = 4.2 U S gal approx).

Tonelada = 20 quintales = 2 032.2 lb av = 921.8 kg.

Vara = 2.75 ft (Peru), 2.841 ft (Argentina), 2.782 ft (Spain).

Estaca (Peru) = 167 meters sq = 27 889 sq meters.

Fanega (Peru) = 1.65 acre (varying locally); also = 141.43 lb av = 64.14 kg; also = 1.599 bushel (in Mex = 2.577 bushels).

Pertenencia, or mining claim (Mexico) = 167.6 m horiz on strike of vein, width of 94.28 to 167.6 m, according to dip.

Weights used for silver and gold in Peru: 3 granos = 1 tomin, 12 tomines = 1 adarme; 16 adarmes = 1 onza; 8 onzas = 1 marco; 2 marcos = 1 libra (= 1.014 lb Spain and Mexico).

1 marco = 50 castellanos = 230.07 gm = 3550.54 gr = 0.507 lb av. 1 onza = 1.23 oz Troy. 1 oz Troy = 6.755 castellanos.

In Mexico, the silver contents of an ore is expressed in MARCOS per CARGA. 1 marco per carga = 6.571 oz Troy per ton.

22. Values of Foreign Coins

ollowing equivalents, in terms of the U S gold dollar, were established by Secretary of the Treasury on Jan 1, 1911, for estimating the value of foreign handise exported to the U S and expressed in such metallic currencies.

Country	Monetary unit	U. S. equivalent
entine Republic	Peso	$0.965
tria-Hungary	Crown	.203
ium	Franc	.193
via	Boliviano	.389
il	Milreis	.546
th America (except Newf'nd). tral Amer. States	Dollar	1.000

Volume, cylinder, comp-air hoisting, 90

Volume, by integration, 1943
specific, of gases, 2049, 2050
of surface of revolution, 1943
units, conversion, 2303
Vol-press-temp in air compression, 1086
Volumes, calculation, 1926–1929
centers of gravity, 1964
determined by leveling, 1204
Volumetric efficiency of compressors, 2034–2036
mine ventilators, 1058
Vortex hydraulic classifier, 1659
Vulcan mine square-sets, 540

Waddle mine fan, 1056
Wager Bradford, monorail, 678
Wages, Anthracite Strike Commission awards, 1366
anthracite stripping, 693
Alaska-Treadwell mine, 1302
Goldfield Consol mine, 1296–1298
Klondike, 827
methods of paying, 1361
Nome, Alaska, 826
S E Mo, 1331
U S and elsewhere, 1357
Wages and Welfare, 1356–1382
Wagon roads, location, 1223
Wagons, capacities, 119
data on, 124, 198
Waihi cyanide mill, 1837
mine, stoping practice, 562
Wales, slate quarries, 526
Walker detaching hook, 972
Wall timbering in square-set stopes, 548
Walling, shaft, 271
Walls, concrete, 2235
retaining, 2231–2236
stone, varieties, 2219
stope, supporting, 504, 511
Ward-Leonard control system, 2173
Wash and change houses, 1369–1371
Wash solution in cyanidation, 1832
Wash-boring, 307
Washers for bolts, 2253
Washery data, 1889, 1890
Washing before cyanidation, 1821
testing, 1795
coal, 1884–1890
drift gravel, 820
ore, 1650
placer gold, 755–757
Washington, hydraulic air compression, 1076
mining laws, 1497
Washoe concentrator flow-sheet, 1714
Wasp cyanide mill practice, 1826, 1835
Waste heat, utilization, 1128
sorting, 1291, 1314, 1316, 1323, 1325, 1337, 1338
stope filling, 560
Waste stope filling, in shrinkage stopes, 589
in underhand stopes, 504
Wastes, domestic, 1376
Water for anthracite preparation, 1862
for chemical work, 1754
column, boiler, 2084
cooling, for condensers, 2092, 2093
diamond drilling under, 347
for diamond drilling, 349
for drilling, 182
drinking, underground, 1407
domestic, purification, 1373–1376
in drift faces, 239
end of pumps, 2098, 2102
erosion, 92
for fighting fire, 1443, 1451
gage for mine ventilation, 1034
for gravity-stamp crushing, 1641
ground-, 95
hammer, 2009
handling in mines, 997
hoisting, 1014–1017
for hydraulic elevators, 790, 791
for jigging, 1679
level, recording, 2016
lining, strength of, 272
loss by seepage, 2014, 2023
measurements, 2131
meters, 2018
mine, sources of, 993
for power plants, 1126
pressure by integration, 1943
prior rights for, 1478
properties of, 1990
rate of engines, 2041, 2076
required for milling, 1348, 1707
right, form of notice, 1523
rings, 997
for round tables, 1687
in shafts, 252, 262, 271
sprays for hammer drill, 1115
supply, 2021–2023
for hydraulic mining, 767
turbines, 2115–2120
velocity in channels, 2020
in ditches, 2013
in pipes, 1999
in pumping, 2101
measuring, 2018–2021
Water-bearing soil, shaft sinking, 283–306
Water-driven compressors, 1071
Water-Leyner hammer drill, 1111, 1112
Water-purifying systems, 1128, 1374–1376, 2085
Water-tube boilers, 1127, 2083
Watt all-steel mine car, 839
defined, 2160
Wattmeter, 2167
Watt-hour meter, 2167, 2197, 2198
Waugh hammer drill, 1110, 1111, 1112
Waves in colliery explosions, 1436, 1437

Weak ore, filled stoping, 564
Wear of Blake ore breakers, 1624
  of diamonds in boring, 355, 356
  of Dodge ore breaker, 1626
  of gyratory breakers, 1628
  of hoisting ropes, 920, 921
  of stamp shoes and dies, 1291, 1297, 1301, 1304, 1308, 1312, 1639
  of track cable, 1570
Weathering of rocks, 81
Webb No 3 shaft, cost, 277
Webber tramway grip, 1571
Wedge, volume, 1928
Wedging crib for shafts, 272
Weg oxygen apparatus, 1448
Weigher, Blake-Dennison, 1705, 1706
Weighing ore for sampling, 1738, 1739
Weight of air, 1035–1037, 1088, 1384
  of a-c generators, 2179
  of belt conveyer, 1611
  of bolts, 2155, 2156
  of cement, 2217
  of comp-air locomotive, 869
  of corrugated iron, 2155
  of cyanide pulp, 1827
  of earth, 120
  equivalent, elec-chem, 2202
  of induction motors, 2185
  of iron bars, 2226
  of materials, 2241
  of minerals and rocks, 1539
  of ore, etc, 988, 1539
  of skips, 970
  of spikes and nails, 2252
  of steam turbines, 2081
  of steel plate, 2154
  of storage batteries, 2205
  of track cables, 1557
  of water, 1990
Weights and measures, 2299–2302
  for assaying, 1753
  conversions, 2303
  metric, 2301
Weirs, flow of water, 1996–1998
Welfare, mine employes', 1369–1382
Well sinking with explosives, 170
Wellman-Seaver-Morgan detaching hooks, 971
  geared hoists, 883
West Africa, diamond drilling, 362
W Australia, handling ore in stopes, 513
  mine development, 458
West mill, Kellogg, Idaho, flow-sheet, 1712
  Virginia, animal haulage, 865
    coal mining practice, 714
    electric power plants, 1124
    gasolene loco, 868
    oil-well drilling, 326
Westfalia oxygen apparatus, 1448
Weston normal cell, 2159
Westphal balance, 7
Westphalia, camp-air loco data, 1121
  turbo-comp tests, 1071
Wet anthracite preparation, 1849, 1852–1853
  concentration, 1672–1692
    vs dry, 1699
  electric cells, 2205
  extraction tests, 1796
  ground, shaft sinking, 273
Wetherill magnetic separator, 1693
Wetting to prevent explosions, 1439
Wheel base for mine cars, 843
  bearings for mine cars, 844
  laws of rotation, 1975
  loads on bridges, 2244
Wheelbarrows, 123, 198
  for underground work, 838
Wheeler turbo-air pump, 2091
Wheeler-Wiggin-Richards classifier, 1667
Wheels for mine cars, 844, 845
  for skips, 965
Whim, hoisting by, 880
Whistle pipe sampler, 1733
Whitcomb hammer drill, 1110
White channel placers, 773, 779
Whitedamp, 1020, 1388
Whiting hoisting system, 893, 908, 911
  steam hoist test, 886
Wickes boiler, 2083
  Bros rock drills, 1104
Wickwire mine, top-slicing, 611
Wico electric lamp, 1415
Wide orebodies, filled stopes, 566–573
  outcrops, law governing location, 1526
  veins, underhand stoping, 505
Width of stope, 483
Wild Goose placer mine, hydraulic elevators, 792–794
Wilfley table, 1680
    model, 1788
William Penn colliery, water hoisting, 1015, 1016
Williamstown colliery sump, 998
Wind erosion, 93
  load, 2242
    in headframes, 926–928
    on tramway towers, 1573
Windlass and whim, 252, 880
  buckets, 949
Windows, house, 2259
Wing chutes, 537
  stulls, 512
Winzes and raises, 472–479
  development by, 458
  sampling, 1528
Wire, electric, 2163–2165
    blasting, 176
  gages, U S, 2154
  ropes, hoisting, 913–924
    strength, 915–917
    tramway, 1569, 1572

Wire screens, factors, 1779
for shaft plumbing, 1243
for transmission lines, 2192
Wire-rope drive, 2144
guides, 944
Wiring, calculation of, 1132
for conveyer motors, 1615
for electric distribution, 2197
for power stations, 1130
underground, 1134–1137
Wisconsin, boring and sampling, 437
Steel Co, steam turbine plant, 2081
zinc mine, gasolene loco, 868
stoping, 496
shafts, cost, 277
Withdrawals of public lands, 1482
Witherell, C S, ore-buying schedule, 1805
Witwatersrand, cyanide practice, 1836, 1839
Deep mine, filling, 682
prospecting, 414
ventilation requirements, 1023
Wabana iron mines, Newfoundland, 502
Wolf safety lamp, 1410, 1412
Wolverine mine, costs, 1338
stoping, 519
Wonder rock drill, 1104, 1113
Wood-lined iron pipes, 1012
pipe, 2006–2008
preservative, 231, 2247
rock drill, 1102, 1105
strength of, 2248–2250
ties for track, 847
varieties and uses, 2246
Wood-stave ore chutes, 668
pipe, 2006
Woodbury jig, 1676
Wooden beams, strength, 2250
columns, strength, 2250
gear teeth, 2135
headframes, 931–935
houses, 1372
mine rails, 846
models of mines, 1264
piles, 2216
poles for elec wiring, 2197
pulleys, 2141
Wooden riffles, 785
tipple, 1875–1881
Work and power, 2024–2028
diagram, 1980
units, 1980
conversions, 2304
of ventilating fans, 1046
Working bond, form, 1522
face record, 1277, 1278
hours in coal mining, 1353
stress, 2210, 2213
in cast iron, 2260
for concrete, 2222
for timber, 2248–2250
Workmen's accident compensation, 1463
Worm gear, 2135, 2136
Wound-rotor induc motor for fans, 1150
Wounds, treatment, 1457–1460
Wrought iron, structural, 2260
Wrought-iron pipe, 2004, 2148, 2149
Wyoming mining laws, 1497

Y-level, 1168
Yellow fever, 1380
Yield, daily estimates, 1272
point, defined, 2209
Young & Son's eccentric transit, 1237
Young's modulus, defined, 2209
Yuba gold dredge, 814
Yukon Gold Co data, 773, 777
gold dredging, 812, 813
placers, 772, 773

Z-beams, steel, 2264
Zaruma filled rill stopes, 581, 582
Zimmermann's fault rule, 90
Zinc for cyanide precipitation, 1817, 1819, 1831, 1832
mining, cost at Joplin, 1332, 1333
ores, 101
assay, 1763
in ores, penalty, 1801
payment for, 1805
precipitation of gold, testing, 1795
treatment of timber, 2247
Zirconium ores, 107
